The story of chili pepper, and the widespread adoption of other innately unpalatable substances, such as black pepper, ginger, tobacco, and coffee, is notable because in most cases, the very same properties that cause innate dislikes become liked, in what are called hedonic reversals. People do not consume chili pepper, like a medicine, because they think it is good for them. They consume it because they like it.

There is not an adequate account of how this happens (reviewed in P. Rozin, 1990), but given the generality of cultural adoption of initially aversive substances and other non-food-related activities discussed below, we briefly discuss the causes of hedonic reversal for chili pepper as a model system. A whole family of accounts links chili pepper ingestion to the many positive physiological effects it produces, including sweating and lowered body temperature, parasympathetic activity (including salivation, gastric secretion, and lowered heart rate), and endogenous opiate release in the brain. In order to learn from these effects (and somehow, via this learning, transform the hedonic response), repeated exposure is necessary. Normally, when an aversive event or substance is encountered, it is subsequently avoided. So one important effect of culture is to produce an environment, social and physical, in which repeated consumption of food with chili pepper in it occurs. Is this a sufficient condition (Zajonc’s [1968] well-documented process of “mere exposure”)?

The answer is clearly “no”; fieldwork and preference tests in the field (reviewed in P. Rozin, 1999; P. Rozin & Schiller, 1980) indicate that while all Mexicans over about age 6 years in a village like the burn of chili pepper, not a single animal in the same village does so. However, the dogs, pigs, and chickens consume the daily garbage, which regularly includes stale staple foods and dishes, and excess salsa (the chili pepper-based sauce that is placed on most savory foods; P. Rozin & Kennel, 1983). The reversal of the innate aversion for chili pepper, and almost certainly other entities, seems to be an almost uniquely human accomplishment, and to involve culture as an essential ingredient.

Field measurements (P. Rozin & Schiller, 1980) indicate that very young Mexican children do not like chili pepper, and that liking for the burn sensation occurs somewhere around 4–6 years of age. There are two reasonable, nonconflicting, accounts. One is social; in the meal setting, the entire family consumes food with chili pepper in it, or with an accompanying sauce to be added to the foods. There is no overt pressure at the table to consume hot pepper. But the young child observes that older siblings and all adults consume it with gusto, and this experience may in some way produce the hedonic reversal.

A second account, which we call “benign masochism” (P. Rozin & Schiller, 1980; P. Rozin, 1990; P. Rozin, Guillot, Fincher, Rozin, & Tsukayama, 2013), puts liking chili together with a whole set of uniquely human activities, in which pleasure is produced by the elicitation of negative experiences and/or emotions (e.g., riding roller coasters, recreational parachute jumping, watching sad movies, and drinking black coffee). The idea is that humans, and only humans, seem to get pleasure out of the fact their body is signaling danger/rejection to them, but they know they are really safe. The case is particularly clear for roller coaster riding. We have some evidence that this might be the case for chili pepper, because we have shown that the most preferred level of “burn” for chili pepper for any individual is the level that is just slightly below the level of aversive pain (P. Rozin & Schiller, 1980; P. Rozin et al., 2013). It is worth noting that humor at experiencing disgust is another possible example of benign masochism.

The important lesson from chili pepper, as an example of learned reversal of innate aversions, is that, at a minimum, it invokes cultural mechanisms at three levels: (1) the availability of the substance or

experience; (2) the continued exposure to it, in spite of its initial negative effects; and (3) in some yet-to-be-fully-understood way, the accomplishment of hedonic reversal.

Milk

Milk is necessarily the first food of mammals. Until the development of animal domestication and then dairying by humans, milk was a unique food available only to baby mammals. In the contemporary human world, milk and derivative dairy products form an important part of the diet in many cultures. It is notably absent from most East Asian and West African cuisines. The cultural history of dairy products shows how biological constraints affect cultural evolution and institutions, and, importantly, how culture affects our biology. It is this dual-direction effect that is the focus of this section on milk.

Since milk is unavailable as a food past nursing in the predomestication environment, it would be problematic to have adult mammals seeking their first food. A number of mechanisms have evolved to accomplish not just the weaning from milk, but some decline in its preference (reviewed in P. Rozin & Pelchat, 1988). The most relevant mechanism is genetically programmed lactose intolerance (Simoons, 1969, 1970). The principal carbohydrate in mammalian milk is lactose, a sugar that is the combination of two simpler sugars, glucose and galactose. Lactose is only found in milk. Lactose cannot be absorbed directly but is broken into its two utilizable subcomponents by the gut enzyme, lactase. This enzyme is present in the gut of virtually all mammals, and is deprogrammed, such that it gradually disappears at about the time of weaning of the species in question. Undigested lactose ferments in the hind gut, producing gas pains and diarrhea, and interfering with absorption of some of the nutrients in milk. These unpleasant symptoms very likely contribute to the weaning process. Preagricultural humans were like all other mammals and therefore unable to utilize milk effectively after weaning.

Domestication made milk available as an adult food. There is convincing evidence, largely from the work of Simoons (1969, 1970), that two very different types of adaptations occurred since the origin of domestication to

encourage the availability of milk and its products in the postweaning human diet. First, cultural innovations adapted to a biological limitation (adult lactose intolerance) by digesting milk outside of the body, breaking down the lactose into its utilizable components before ingestion. This was done with microorganisms, resulting in products such as cheese and yogurt. These, appropriately termed “cultured” products, make the carbohydrate in milk utilizable and bypass the negative symptoms.

A second set of biological adaptations occurred subsequent to the rise of dairying. In a group of cultures, primarily from Northern Europe but also including some pastoral groups in Africa, the availability of dairy food set up a situation in which the adult ability to digest lactose was adaptive. There is a single gene mutation that, when it occurs, blocks the deprogramming of lactase production at weaning. In these cultures, the occurrence of this mutation improved survivability and gradually, the gene frequency rose. The result is that most people of Northern European origin (and a few African groups) retain their lactase and can drink uncultured milk throughout their lives. Hence, a cultural advance changed the adaptive landscape for humans, and induced a genetic change in some groups of humans.

There are many issues related to dairy products that may engage cultural psychology, but we will not deal with them here. One is why Chinese cuisine, one of the world’s major and most innovative cuisines, includes no dairy products. This may have a cultural–historical account; the Chinese were exposed to milk by the Mongol invaders, and it may be that their aversion to the Mongols extended to the food of the Mongols.

MEAT

Meat should be a subject of special interest to psychologists, because in most cultures, it is not only one of the most loved but also the most tabooed categories of food, comprising a quintessential example of the state of ambivalence (Fessler & Navarrete, 2003; Ruby et al., 2016). As a dense source of protein, fat, and essential minerals, meat is highly valued, and in many cultures, the ability to consume large amounts of meat has traditionally been a marker of wealth, power, gender, and status (Adams, 1990; Fiddes, 1991). At the same time, meat is more likely than plant-based

foods to harbor microorganisms that can infect humans, and these pathogens are often harder to detect than the toxins found in plants (Hladik & Simmen, 1996; Schantz & McAuley, 1991). Obtaining meat involves hunting and killing other animals, an act that requires great skill, and is at the same time morally questionable. The anthropologist Stanley Tambiah (1969), elaborates some of these points in a well-known article entitled “Animals Are Good to Think and Good to Prohibit.” He might as well have replaced the word *think* with *eat*. Indeed, research suggests that in many cultures, the killing of animals (for meat) evokes feelings of guilt and tension (Piazza et al., 2015; Plous, 1993; Simoons, 1961/1994). People are often motivated to deal with these negative feelings by dementalizing the animals that they eat, or by dissociating meat from its animal origins (Kunst & Hohle, 2016; Loughnan, Bastian, & Haslam, 2014; Rothgerber, 2013; Ruby & Heine, 2012).

Meat is the only general category of foods that is widely prohibited across cultures. Almost all objects of food disgust, cross-culturally, are animals or animal products (Angyal, 1941; P. Rozin & Fallon, 1987). This can, perhaps, be related to the role of disgust in pathogen avoidance. Meat may also enlist, more than plants, the “you are what you eat” principle (eat an animal and become animal-like; Nemeroff & Rozin, 1989). Of course, cannibalism, often the most negatively regarded human food practice, is a special example of meat eating.

Across many cultures, meat (particularly mammal meat) is linked with conceptions of masculinity and is often considered a “man’s food” (Adams, 1990; P. Rozin et al., 2012; Ruby & Heine, 2011). In preindustrial societies, meat (particularly mammal meat) is often preferentially distributed to high-status individuals, typically middle-aged men. In many developed countries, men hold more positive attitudes toward meat, consume it more often, and are more likely than women to believe it is an essential part of a healthy diet (for a detailed review, see Ruby, 2012).

Just as there is a long history of humans’ ambivalence about eating meat, there is a long history of people choosing not to eat it (i.e., vegetarians). “Vegetarianism” has proved rather difficult to study, as definitions of the term vary widely among both researchers and laypeople. Although *vegetarian* is defined as by the *Oxford English Dictionary* as “the practice of not eating meat or fish, especially for moral, religious, or health reasons,”

research from many cultural contexts (e.g., United States, Canada, Switzerland, United Kingdom) indicates that many self-identified vegetarians report eating poultry and fish, and even sometimes red meat. As such, the exact prevalence of vegetarianism is difficult to quantify, unless one specifically defines the term when conducting polls and surveys.

In the Western World, abstention from eating meat due to spiritual and ethical concerns about killing and eating animals can be traced back to the writings of Pythagoras and Plato, with arguments for the health benefits of a meat-free diet only emerging in the 1800s, and arguments about the environmental sustainability of a meat-free diet arising in the past few decades (Spencer, 1993; Whorton, 1994). A broad body of research indicates that, compared to their omnivorous peers, Western vegetarians are more likely to be women; to be concerned about animal and environmental welfare; to more strongly endorse universalistic values (e.g., concern for equality and social justice); and to oppose authoritarianism, social hierarchies, and the use of violence. Although the prevalence in many Western cultural contexts has been growing (e.g., recent estimates: Germany ~9%, Canada ~8%, Ireland, ~6%, USA ~5%; Ruby, 2012), vegetarians (outside of India) remain a small minority, and most elect to become vegetarian at some point in their lives rather than being raised as such.

In contrast, vegetarianism in Indian cultural contexts has been a prominent practice for centuries and is far more common (recent estimates range from 20 to 42%), making it likely that there are more vegetarians living in India than in all other countries combined. Here, vegetarianism has historically been associated with purity, status, and tradition, with most vegetarians being born into the practice. The anthropological literature indicates that the avoidance of meat has mostly been motivated by ascetic and spiritual concerns, linked to the belief that eating meat can pollute the body and spirit, although, in more recent years, concern for animal welfare and environmental sustainability have been growing in prominence (Caplan, 2008; Preece, 2008; Ruby, Heine, Kamble, Cheng, & Waddar, 2013). Despite the prevalence of vegetarianism in India, psychological research on the topic remains sparse, and is sparser still in East Asian, Latin American, and African cultural contexts.

INSECTS AS HUMAN FOOD

As concerns for food security, environmental sustainability, and animal welfare increase, more attention is being paid to the idea of making insects a major food source for more humans. A great deal of work has emerged in this domain in the past decade, covering this prospect from anthropological, economic, entomological, environmental, and nutritional perspectives (Paoletti & Dreon, 2005; Ramos-Elorduy, 2009; Yen, 2009). Arnold van Huis and colleagues (2013) provide a comprehensive account of this work. These and other sources indicate that many species of insects are nontoxic, highly nutritious (particularly in terms of protein, fats, and essential minerals), and more environmentally sustainable than conventional domesticated animals (e.g., more efficient conversion of plant to animal calories, less water usage, lower greenhouse gas emissions). People are generally less concerned about the ethics of killing insects compared to animals more commonly killed for meat. Also, insects can easily be raised in compact but “natural” settings, and death can be produced simply by cooling, a process that naturally occurs, temporarily, in places with cool evenings.

Although insects are a valued (and readily eaten) food source for about 1 billion people, for many, the idea of eating insects elicits intense disgust (Ruby, Rozin, & Chan, 2015). Recent work suggests that disgust is the main barrier to insects being consumed by a broader segment of the population. A growing number of scientists, chefs, and food manufacturers are experimenting with ways to make insect-based foods more psychologically appealing and integrated into familiar cuisines for nonconsumers. Currently, these foods are rather expensive, as are the insects themselves, and much work is being done to make production more efficient and scaleable (Deroy, Reade, & Spence, 2015; Ramaswamy, 2015).

FOOD AND RELIGION

Religions, often seen as divinely ordained, are also systems that may only be understood by integrating biological and cultural approaches, as religions themselves reflect biological influences (e.g., responding to local ecological pressures; innate avoidance of uncertainty) and cultural processes, which

change over time via cultural evolution (Northover & Cohen, 2018; D. Wilson, 2002). Religions, as systems of rules, beliefs, values, and practices, may be conceptualized in the same way that cultures are (A. Cohen, 2009).

While there are hundreds or even thousands of religions, our thinking and examples below come from what typically are regarded as the major world religions, in terms of adherents. The one exception that we add is Judaism; although it has less than 20 million adherents, it is foundational for two of the world's major religions (Islam and Christianity), and, like Hinduism, engages food and eating in a prominent way.

A major part of many religions involves what one can or cannot eat (Muslims may eat beef but not pork), when one can eat or not eat (Muslims cannot eat during the day during Ramadan), what combinations of foods can or cannot be eaten (e.g., although meat and dairy products may be eaten separately by Jews who keep kosher, their combination is forbidden), who may eat certain food (only people in a state of grace can eat the communion wafer in Catholicism), what foods are sacred (prasad, food donated to a priest and hence to a deity in Hinduism, is then partially returned to the donor and is blessed or sacred), and some foods that have symbolic, ritual functions (e.g., the red wine in the Catholic Communion becoming the blood of Christ). Furthermore, eating (ritual) often rises to great importance, as well as the food itself. Catholic mass and Jewish Passover involve more than special foods; they involve the way they are presented and consumed.

People don't just vary in their food practices or thinking by belonging to different religions, but food practices and thinking might also vary based on whether people are fundamentalist/orthodox or not. In some ways, orthodox/fundamentalist practitioners of different religions (e.g., Hinduism and Judaism) may be more similar to each other than to less orthodox member of their own religion (Jensen, 1998). Thus, orthodox Hindus and Jews are similar in their great concern for food prohibitions and contamination. Orthodox Hindus and Jews might share a sense that food is related to divinity. On the other hand, less orthodox individuals in any particular religion may share some food attitudes or practices with more orthodox persons from the same religion. For example, even less orthodox Hindus may avoid beef. Even atheists commonly have food practices related

to a secular and moral worldview, such as when they are vegetarian for environmental or animal compassion reasons.

An approach within evolutionary psychology concerned with “fundamental motives” might give some clues about why some religions have certain food practices, and why some individuals adhere to them and others don’t. This approach holds that all humans have a set of fundamental social motivations, including self-protection, disease avoidance, coalition formation, status seeking, mate acquisition and retention, and offspring care (Kenrick, Li, & Butner, 2003). All of these have to be successfully managed to be evolutionarily successful. This framework has been applied to thinking about religion and food (Johnson, White, Boyd, & Cohen, 2011). As different ecologies have different affordances, this could help explain why religions that formed and evolved in different parts of the world have different rules (one might avoid specific food disease vectors if one is in a place with a lot of the relevant specific diseases), and why individuals show different levels of adherence (one hypothesis could be that immunocompromised people might adhere differently than people with robust immune systems). As we have discussed earlier, the disgust system is ideally suited through preadaptation to evolve into the moralization of purity (Horberg, Oveis, Keltner, & Cohen, 2009), and purity is often embodied in consuming or forbidding foods (see Wilson, 2002, for an excellent treatment of religion and cultural evolution).

However, disease avoidance and purity don’t explain the bulk of religious food prohibitions and ritual, or why practices persist long after the threat can be effectively managed (to the extent that religious pork taboos have something to do with trichinosis, trichinella are killed by cooking, but pork avoidance is still practiced by many). Disease avoidance is just one reason why religions might have instituted some food or eating rules. Sometimes people avoid foods that would be “good” for them for religious or cultural reasons (e.g., among the Hua of Papua, New Guinea, adolescent men avoid eating soft, reddish fruits due to a belief that these fruits are female-related and could have a feminizing effect; Meigs, 1984).

Some religions seem to have many food rules (e.g., Orthodox Judaism) and others, relatively few (e.g., American Protestant Christianity). One thing that may be relevant here is that some religions are religions of descent (e.g., Judaism, Hinduism), where one is born into the religion, and others are

religions of assent, where one belongs if one assents to the appropriate beliefs (e.g., Islam, Christianity; A. Cohen & Hill, 2007; Morris, 1996). Descent religions would be expected to have more bodily/purity and hence food concerns. This might be the case because, in descent religions, one is likely to be more accustomed to thinking about issues of purity and contamination (e.g., “That person appears to be Jewish, but does she actually have Jewish biological parents?”). Judaism and Hinduism have many food prohibitions and a great concern with contamination of good foods by small amounts of forbidden foods. The Hindu caste system, deeply related to Hindu doctrines related to purity, is enacted primarily in the domain of food and eating transactions.

Food prohibitions and practices may have the important social function of socially binding people in a religious community together, and differentiating them from other communities (e.g., for Judaism; A. Cohen, Gorvine, & Gorvine, 2013). Food practices can often serve as a costly signal of commitment to one’s group, increasing within-group cooperation and trust, and differentiating the group from other religions/communities. Furthermore, the descent religions tend to be exclusive and do not encourage conversions, so their food rules would insulate them to some degree from those outside their religion. However, the assent religions seek conversions, so the absence of elaborate food rules might encourage more mixing with others, who are potential converts.

New findings indicate that even costly signaling (e.g., by avoiding certain religiously prohibited foods) by outgroup members causes them to be trusted more by people within the religion in question; for example, a Muslim who adheres to halal restrictions is trusted more by Christians than a Muslim who flouts those restrictions (Hall, Cohen, Meyer, Varley, & Brewer, 2015). Perhaps adhering to food restrictions is not only seen by the ingroup as a signal of ingroup commitment but also as a signal of general good character or self-control. Adhering to religious food practices, such as fasting or avoiding highly palatable foods, can take a lot of self-control (Mathras, Cohen, Mandel, & Mick, 2016). People vary in how much self-control they have, so this might be one reason why some people adhere to rules and others don’t.

These are just a few biological and cultural factors that might explain how religious food practices come to be, why they differ across religious or

other cultural groups, and why some people adhere to them and others don't. The area of religion and food is obviously fertile ground for cultural psychology.

SUSTAINABILITY AND THE MORALITY OF EATING: THE MODERN OMNIVORE'S DILEMMA

Michael Pollan's (2006) best-selling book, *The Omnivore's Dilemma*, brought to the fore a wide range of concerns about the consequences of our food choices, especially in the developed world. Since wealthier people (most of whom live in the developed world) spend a much lower percentage of their income on food, it is possible for them to stand back from daily meals and be concerned about longevity, as well as a range of potentially moral concerns about food choice. Issues of sustainability are also of great import in the developing world, but for many of these people, in or near poverty, nutritional survival, in a relatively short-term time frame, can dominate food choice, compared to thinking about the broader consequences of eating.

We enumerate here four basic, new concerns that constitute part of what we call the "modern omnivore's dilemma."

The first modern concern has to do with the effects of the modern food system on long-term health, well-being, and life expectancy. Barry Popkin and colleagues (Popkin, Adair, & Ng, 2012) have highlighted what is called "the nutrition transition," affecting the whole world to varying degrees, in which traditional home-cooked food is replaced by eating away from home, with sharp increases in the intake of sugars and a number of processed foods. At the same time that this is happening, and partly as consequence, malnutrition is declining; this is partly the result of disease control and wealth increase, but also because, through modern agriculture, some foods have become cheaper. These same forces that operate to reduce malnutrition are also involved in the worldwide increase in obesity.

The second modern concern has to do with the ethics of eating animals, from the point of view of animal welfare. What is the place of animal rights in decisions about what animals to raise for food, how to treat them, and how to kill them?

The third modern concern has to do with the effect of food choice on the biosphere and the planet. Stern and Dietz (1994) measured three spheres of human concern: egoistic, altruistic and biospheric. Greater wealth allows more attention to the latter two spheres. This concern manifests most clearly in concerns about climate and pollution, related to food.

The fourth modern concern relates to what has been called “the industrialized diet” (Winson, 2014). This involves concentration of food production, marketing, and retail sales primarily under the control of a relatively small number of large corporations, with a reduction in fresh foods (which are hard to mass-market), and a focus on inexpensive processed foods, but at the same time, the creation of many “microvarieties” (e.g., in soda or yogurt flavors). The modern food system, at the same time that it has increased food safety and decreased food prices, has also produced some outcomes that might be construed as moral: the decline of small, family-based farms; the possibility that efficiency and profit may displace care for the environment and animal welfare; a decrease in the formerly close relation between the origin of food and the consumer; and increased processing of food. For many people, at least in the Western World, “natural” has become a feature of food that has moral qualities, and that has produced a major increase in availability of food products labeled as natural or organic and gives rise to morally based opposition to genetically engineered foods (Scott, Inbar, & Rozin, 2016).

Some of the issues raised in *The Omnivore’s Dilemma* (Pollan, 2006) and other books (e.g., Goodman & Redclift, 2002; Thompson, 2015, Winson, 2014) can be debated in terms of the facts of the matter and whether the concerns are truly moral. For example, to what degree are we morally responsible for killing animals whose existence is a result of our intervention? Is animal food inherently more costly to the earth, even if it comes from natural pasture that cannot support traditional or modern agriculture? How do we compare the benefits of the pleasure of eating against the long-term health or moral effects? Is it okay to spend \$50 for a meal, when if one spent \$10, one could get adequate nutrition, and also feed 40 malnourished children in the developing world for a day with the other \$40 (Singer, 2015)? Is it okay to grow and consume high-yield crops that result from genetic engineering?

In the developed, Western World, there is strong opposition by many people to the growth and consumption of genetically engineered food. This concern is higher in Western Europe than in the United States. Although consequential arguments are often invoked by opponents (e.g., unknown side effects), analysis of survey results suggests that the majority of opposition is moral: Genetic engineering of foods is just morally wrong (Scott et al., 2016). Nature can be conceived to be a sacred value; hence, interfering with it is immoral.

These are vexing questions that motivate major dietary changes (e.g., conversion to vegetarian or vegan diets) in some and are not compelling to others. These concerns vary in importance in different countries, as well as in people differing in education and social class. The modern omnivore's dilemma is relevant to all humans, and the planet. As wealth increases, it will become part of the food-choice world for more and more people.

Globalization and the Role of the Environment and Social Class

The single most important determinant of food choice is the environment; if a food is not available, it cannot be chosen and consumed. Traditionally, before food transport capacities, international trade, and globalization, ecological/environmental factors almost completely determined availability. The idea that people eat what is available does not excite the imagination, and it does not encourage psychological theory. It has not been given much attention in the psychological study of food and eating, which is perhaps a manifestation of a “fundamental attribution error,” that is, a minimization of cultural environmental effects. In most psychological studies, what is at issue, given the presence of food or food choices, is how do people think and behave? However, recent work on food, much from within psychology, has focused on the environment (in particular, portion size) as a main determinant of food intake (e.g., Hill & Peters, 1998; Rozin, Kabnick, Pete, Fischler, & Shields, 2003b; Wansink, 2004). Cultural differences have been documented in portion size (Rozin et al., 2003b), and American historical trends towards larger portion size have been described (Rolls, 2003; Young & Nestle, 1995). Thus, portion size and more general issues of food

availability and context (Meiselman, 1996) fall squarely into the domain of cultural psychology.

Through globalization, the food world is homogenizing, especially because of great advances in the storage and transport of foods. For complex reasons that are beyond the scope of this chapter, much of the world wants to be more like Americans, a desire that has become more concrete and informed by widespread exposure to the Internet. American and other Western foods are seen as desirable and prestigious. Recent research in a traditional, medium-size city in India (Vijayapura) indicates that adolescents consider Western foods eaten outside the home to be more prestigious than traditional foods (Maxfield, Patil, & Cunningham, 2016).

People also migrate more with increased globalization. Examining the dietary changes of people from Sri Lanka and Pakistan who moved to Oslo, Wandel, Raberg, Kumar, and Holmboe-Ottesen (2007) found that both groups reported certain changes, such as consuming less beans and lentils. Age was negatively correlated with more butter and margarine consumption, and higher integration correlated with consuming more high-fat foods.

Social class is a major determinant of food choice. Cultural psychology would do well to attend to social structure and social class, because these are psychologically important manifestations of culture (A. Cohen & Varnum, 2016; Kraus, Callaghan, & Ondish, [Chapter 27](#), this volume). For example, the social class structure of Hindu India has enormous influences on food transactions, as historically mediated by the caste system (Appadurai, 1981; Marriott, 1968). Changes in food habits within any culture usually take place over decades or even centuries, and typically move from one class to another. For example, in Europe, chocolate spread from upper to lower classes, and in the United States, sushi has moved from upper to middle classes. Economic factors (initially high cost) partly account for these class shifts, as well as a general tendency for lower classes to imitate the behavior of higher classes. On the other hand, some foods, including chili pepper in the United States, and more generally, highly spiced foods, have often moved from lower to upper classes. The popularity of ethnic cuisines among high-socioeconomic-status Americans in recent decades represents a movement from lower to higher classes.

Finally, in modern American society, principally among more educated and wealthier groups (Leichter, 1997), the idea of healthy eating and exercise has taken hold. This often acquires a moral tinge, what Solomon Katz (1997) has called “secular” morality. There are indications that the attraction of healthy eating may spread across countries and class.

THE INVERSION OF THE ANCESTRAL FOOD WORLD AND THE INCREASE IN OBESITY

A particular problem of general interest to cultural psychology has to do with the stresses and dislocations that are occurring in human life as a result of major and rapid cultural changes, especially in technology. We are, both biologically and culturally, adapted more to our ancestral food environment than to our very recently developed world food environment. Technological advances, especially in the food systems of the developed world, have resulted in inversions of some biological adaptations that may be maladaptive in the modern food environment. Some of these changes are presented in [Table 17.2](#). An ancestral environment in which food was in relatively short supply has been replaced by a modern environment in which cheap food is abundant and always available. An ancestral environment that offered a modest variety of potential foods mixed with many acutely dangerous potential foods has been replaced by an environment offering an extraordinary range of safe food choices. In the ancestral environment, the foods available were evolved under complex adaptation pressures and were rarely (except for animal foods) very calorie-dense; in the contemporary environment, foods with extraordinary calorie density and extraordinarily appealing sensory properties are available; chocolate is a prime example. There is nothing so palatable or calorie-dense in the natural plant world. In the ancestral environment, we had to work to obtain food; in the contemporary environment, minimal calorie expenditure is necessary.

TABLE 17.2. Contrasts between the Ancestral and Contemporary Developed World Food Environments

Feature	Ancestral environment	Contemporary developed world environment
Availability	Limited	Wildly abundant
Variety	Limited	Extraordinary
Super foods (e.g., chocolate, ice cream)	Nonexistent, except for animal foods	Widely available via technological advance (e.g., chocolate)
Energy expenditure necessary to obtain food	Substantial	Minimal
Cost	Substantial in terms of time and energy expenditure	Minimal
Consequences of foods: Epidemiological revolution	Apparent within hours of ingestion	Not apparent at all, culturally informed about effects decades later
Suitability for evaluating foods	Adapted to short-term consequence evaluation	Inability to process and understand complex, long-term food risk information
Food preparation	Extensive	Prioritizing of convenience

In the ancestral environment, there was a rather close temporal link (measured usually in hours) between ingestion of a food and appreciation of its consequences (e.g., satiation and if it contained toxins or pathogens). In the contemporary, developed world environment, acute risks of imbalance or toxicity are minimized by cultural means, such as cuisine, sanitation systems, and preservatives. The food risks in contemporary, developed cultures are generally remote; diet is thought to affect differences in life expectancy that result from particular patterns of food choice; these are measured in decades, not in hours (e.g., heart disease). The epidemiological revolution is largely responsible for this change. Only in the contemporary environment do we get information, in the form of risks or probabilities, from epidemiology and other cultural resources of the long-term effects of dietary patterns. We have not evolved to appreciate or make this sort of evaluation; we didn't originally live that long, and the short-term effects of

foods were our predominant concern. Technology has advanced faster than our ability to adjust to it. Most individuals are not educated in even the basics of probability or about the nature of science; hence, they are unable to evaluate the importance of communicated information about risks. Thus, the cultural transformations that occurred largely in the later 20th century have rendered our biological heritage, finely tuned to our ancestral environment, either irrelevant or harmful.

Modern food technology and the modern car-based environment have fostered a situation in which convenience is a prime commodity. Time scarcity is another effect of modernization that affects food and eating. Feeling that time is scarce might make people less likely to prepare food at home, which, again, might mean less healthy choices; people are also decreasingly likely to have meals as a family, which has important social implications (Jabs & Devine, 2006).

In these cases, it is likely that the inherent and biologically predisposed laziness of all animals, including humans, is being catered to more and more effectively. It may soon be possible to accomplish eating, entertainment, and other major activities with a minimum of energy expenditure. In the meantime, technological advances have greatly improved the safety and shelf life of foods, introduced a massive variety of highly palatable foods, cut food prices, and made it easy to deliver any type of food almost anywhere in the world. Food is a major area for the study of globalization. The successful penetration of McDonald's into vastly different cultures argues for important food universals (Watson, 1997).

The result of these mismatches, primarily in the developed world, has been an increase of obesity and degenerative diseases, and widespread dieting and concern about eating a healthy diet. In the ancestral environment, it is adaptive for all animals to expend as little energy as possible to obtain adequate nutrition. This is because energy expenditure requires more energy intake, and energy intake itself consumes energy and increases the probability of being prey for other species. Furthermore, in the natural world, there is generally a bias to consume food when it is available, since it is often scarce, and undernutrition is a greater threat than overnutrition. Our biological tendencies to eat when food is available, and to expend as little energy as possible, have become problematic in the modern

developed world, where food is palatable, plentiful, and available with minimal energy expenditure.

One result of all of these forces, particularly in the United States, is a great ambivalence about eating, with concerns about obesity, long-term health, and appearing slim tempering the potential enjoyment of a highly palatable, omnipresent, and inexpensive food world (Rodin, Silberstein, & Striegel-Moore, 1985; P. Rozin, Bauer, & Catanese, 2003a).

France–United States Contrasts in Reaction to the Inverted Food World

Fischler and Rozin, along with a number of students, have examined how France and the United States have dealt with the mismatch between the ancestral and contemporary, developed world food environment. They claim that France has been more successful in creating or maintaining compensatory cultural institutions (P. Rozin et al., 1999; summarized in P. Rozin, 2006a), because traditional features of cultural food-related and other institutions in France offer a better buffer to the changes in the food environment. The evidence for greater success in France is the substantially lower level of obesity in France (about half of the U.S. rate), and a notably lower incidence of death due to cardiovascular disease. The French situation is more successful than that in the United States for many reasons.

1. The French food environment discourages overeating by offering smaller portion sizes and making between-meal snacks less available (P. Rozin et al., 2003b).
2. The cultural geography of living styles in France, including especially the availability of food sources (stores) locally and within walking distance of most homes, and the greater inconveniences and expenses associated with the use of automobiles, probably lead to greater energy expenditure in daily life in France.
3. The traditional French attitudes toward food focus more on the experience of eating and less on the (health) consequences of eating, which leads to less conflict and worry about eating, and more pleasure (P. Rozin et al., 1999).

Certain deep differences in cultural values with respect to food tend to reduce the impact of the easy availability of inexpensive, varied, and highly palatable foods (P. Rozin, 2006a; Stearns, 1997). These cultural values include the following:

- An emphasis on moderation as the reigning principle for eating in France, as opposed to abundance in the United States (P. Rozin, Remick, & Fischler, 2011). There is a related emphasis on food quality in France and food quantity in the United States.

- Collective food values are more prominent in France, whereas individualized food values are prominent in the United States. This may result from the strong individualism/Protestant traditions in the United States (Markus & Kitayama, 1991). As a result, Americans prefer to be offered a much wider variety of minor variants of the same food and are much more inclined, in a restaurant, to do their own mixing and matching of main meat dish and vegetable accompaniments, and more individualized seasoning of foods (salt, pepper, ketchup, mustard, etc.). The nutritional wisdom in many cuisines, which has supported success across generations, is to some degree abandoned, under assault from very sweet, fatty, and salty foods.

- Americans are more motivated to spend money and arrange their lives to minimize effort and maximize convenience, which has the result of spending less energy. The French are more inclined to spend more money on maximizing joy, that is, having memorable and relatively unique experiences. This corresponds to the important distinction between comforts and pleasures made by Scitovsky (1976/1992) and P. Rozin et al. (2011). Americans are more inclined to conceive of health as heavily influenced by environmental influences (e.g., electric power lines, environmental toxins, foods), while the French see health more as a matter of internal balance (Leeman, Fischler, Rozin, & Shields, 2011; Payer, 1988). This framing appears in the beliefs of both doctors and laypersons.

- The family meal is a more central, perhaps even sacred entity, in France. Typically, main meals take longer, are not accompanied by accessory activities (e.g., watching television), and all family members above the age of

infants consume the same food. These factors can increase the amount of food experience and pleasure, without increasing actual intake.

In short, the greater success of the French in resisting both inactivity and the promotion of overeating in the modern world results from a combination of differences in cultural values and in the arrangement of the environment. Most of the differences described earlier operate to preserve the pleasures of eating, reduce exaggerated worries about eating, and reduce the incidence of obesity in the French, as opposed to Americans. It does not seem that the French have developed better compensatory mechanisms for the modern food environment; rather, it is that food institutions already in place increase resistance to these changes, and these institutions are not as eroded by the modern world as they are in the United States.

FOOD AND SEX

Food plays a special role in cultural psychology because of the ways cultures have transformed the food domain. In contrast, sex plays a more prominent role in evolutionary psychology, because there are many basic similarities in sexual behavior in the ancestral and modern environments. Yet there are important and fundamental similarities between these two domains. From the point of view of behavior, food is the critical domain for individual survival, and sex, for species survival. In both domains, there is great sensitivity about what gets into the body; there is great pleasure when the “right” stuff gets in, and great aversion, fear, and disgust when the “wrong” stuff gets in. Contamination and purity are important in thinking within both domains. Both sex and food involve sharing substance with another person. This is obvious for sex (and may include shared saliva). For food, shared substance occurs in three senses: eating a food prepared by another person, eating together with another person (perhaps from the same plate or taking bites from the same entity) and, in societies that practiced cannibalism, eating another person. Alan Fiske (personal communication, 1990) has pointed out that eating is commonly used as a metaphor for sexual relations in many cultures, and that rules concerning food and sex are often either parallel or mutually determinative. Meigs’s (1984) analysis of the

food taboos of the Hua of Papua New Guinea is an exemplary demonstration of mixed nutritive and sexual meanings of foods. Foods are believed to be vehicles for “vital essence,” deriving both from their origins and the people who have handled them. There is great concern that males going through pubescence be protected from feminization by foods. Hence, they are not allowed to consume any food raised or prepared by a fertile woman. Furthermore, a whole set of foods that are believed to be feminine, and hence feminizing, are prohibited during this period. Meigs assembles a list of such foods and notes that, as a group, they are reddish in color and soft in texture.

Sex and food each have their relevant aperture, though the mouth, in many cultures, is shared in its food and sex functions. Parallels between the vagina and the mouth appear obvious, including common terminology (labia and lips). At least in American English, there are important metaphorical exchanges of food and sex words. *Eat* has sexual connotations, and the word *meat* is sometimes used to refer to people in a sexual context and also to the penis. Finally, the high sensitivity of women to vaginal intrusion by foreign and potentially contaminating objects parallels the sense of oral intrusion for such objects for both men and women (P. Rozin, Nemeroff, Horowitz, Gordon, & Voet, 1995).

MEASURING AND ASSESSING THE MOTIVATIONS, MEANINGS, AND MANNERS OF FOOD AND EATING

It would be desirable to have scales that measure all of the important aspects of food and eating in culturally appropriate ways. Culturally appropriate measurement has been a general, so far not fully accomplished, goal of cultural psychology. There are some promising measures that represent progress in the food domain. Across a number of European cultures, Grunert, Dean, Raats, Nielsen, and Lumbers (2007) have created and standardized a measure of satisfaction with food-related life. Examining the food world broadly, Scholderer, Brunsø, Bredahl, and Grunert (2004) have developed a food styles measure and applied it across many countries in the European Union. The five domains sampled are shopping, the attributes

sought in a food, the modes of preparing food, consumption situations, and purchasing motives. An influential measure of the motives for food choice, the Food Choice Questionnaire (FCQ), was developed in the United Kingdom and samples nine types of motives (Health, Mood, Convenience, Sensory Appeal, Natural Content, Price, Weight Control, Familiarity, and Ethical Concern; Steptoe, Pollard, & Wardle, 1995). Prescott, Young, O'Neill, Yau, and Stevens (2002) used this instrument with a sample of female consumers in Japan, Taiwan, Malaysia, and New Zealand. Confirming a common finding in prior studies, sensory appeal was the predominant motive in New Zealand, whereas price and health were more salient in the Asian samples. Measurement of the Steptoe et al. (1995) motives for eating were expanded and modified to include 15 motives (Liking, Habits, Need and Hunger, Health, Convenience, Pleasure, Traditional Eating, Natural Concerns, Sociability, Price, Visual Appeal, Weight Control, Affect Regulation, Social Norms, Social Image), and validated in Germany, resulting in The Eating Motivation Scale (TEMS; Renner, Sproesser, Strohbach, & Schupp, 2012). Lindeman and Vänäänen (2000) expanded the single ethical scale in the FCQ by introducing three subscales: Ecological Welfare (Animal Welfare + Environmental Protection), Political Values, and Religion. Across most studies, with data coming primarily from Western Europe, sensory appeal (liking), health, convenience, and price usually emerge as principal motives. Quality/freshness, probably related to sensory appeal, has emerged as important in a study of 15 European Union countries (Lappalainen, Kearney, & Gibney, 1998).

In a series of studies, Guerrero et al. (2012) used free associations, sorting, and other tasks to explore the idea of traditional foods, relating this particularly to their origins, across a number of European countries. In a study that extended well beyond Western Europe (Brazil, China, France, Portugal, Spain, Uruguay, and the United States), Ares et al. (2016) employed 31 questions that probed different ways that food may foster well-being (with respondents expressing degree of agreement with items such as “It makes me feel excited” or “It is good for my soul”). These 31 features were rated for each of nine common foods (e.g., coffee, fish). The largest differences across countries were for items related to emotional and spiritual aspects.

We hope that the existing measures will be consolidated and used to assess a wider range of cultures, including more and more individuals who have not yet become connected to the Internet. We also note that two areas have not yet been assessed: the multiple meanings of food (but see Arbit, Ruby, & Rozin, 2017) and the highly variable manner of eating, or food etiquette.

FOOD SOCIALIZATION: LEARNING ABOUT FOOD AND EATING

Weaning and Toilet Training

With breast-feeding and careful monitoring of the human infant by its mother, there is little that can go wrong in its food world in the first years. Evidence suggests that for the first year or two of life, children will put anything they find into their mouths (P. Rozin et al., 1986b). This potentially dangerous tendency is neutralized by familial vigilance. It seems that the most important thing a child has to learn in the early years is what *not* to eat.

Freud correctly noted two of the major events of early childhood: weaning and toilet training. One is about food, and the other is a consequence of eating. Weaning is a necessary event, and toilet training, though not literally necessary, is universal. Both involve denying a child a pleasure, and both present challenges to both parent and child. Both problems are solved in very diverse ways in different cultures, at different ages, with different degrees of attention and harshness. Because Freud saw these two events as central in the formation of personality, they received attention in a cross-cultural context for at least a generation in the field of anthropology (Whiting & Child, 1953). The consequences of types of weaning or toilet training are not yet well established, but it does seem that the enormous variation in timing and the way different cultures do this does not result in the major types of personality differences that Freud predicted. Although weaning and toilet training are major milestones in early life, developmental psychology in the last part of the 20th century paid scant attention to these two fundamental processes (P. Rozin, 2006b).

Eating

The acquisition of table manners is another important aspect of food socialization that has been little studied by psychologists. Birch, Billman, and Richards (1984) reported that the category of special foods eaten at breakfast in the United States becomes distinctive and separate for children in the later preschool years. P. Rozin, Fallon, and Augustoni-Ziskind (1986a) reported that until the later preschool years, children in the United States do not understand or incorporate a variety of food-mixing prohibitions; thus, if the young preschool child likes food *A* (e.g., steak) and food *B* (e.g., ice cream), he or she will like *A + B* (steak and ice cream). Cuisine is not that simple, and there are many senses of “appropriateness” that must be acquired (Schutz, 1989).

PREFERENCES: FORMATION AND TRANSMISSION

Food is one of the domains in which preferences are particularly salient. It is quite remarkable that although preferences for food, music, and a wide range of activities are very important parts of life (and economics), they are studied little by psychologists, cultural or otherwise (P. Rozin, 2006b). The question for all preferences is, how do they get formed? What makes us like some things and dislike others? The food domain is a natural place to study this, because there are so many food preferences, they are public, and they are usually open for discussion (unlike, e.g., sexual preferences). Surely, one of the major distinctive features of a culture is its cuisine and associated food preferences. If we know someone is particularly fond of rice and soy sauce, we can make a good guess that they are from East or Southeast Asia. While there are large cross-cultural differences in food preferences, there is also wide variation within culture (for an informed and readable discussion of taste preferences in a cultural context, see Prescott, 2012), probably driven by a combination of genetic factors and learning history.

Given the generalist background of humans, it is unlikely that most preferences would be accounted for solely in terms of genetic endowment. A major alternative is the early environment as controlled largely by the parents. Of course, the human mammal would be poorly served by a

tendency to develop strong and permanent preferences for early foods. This would lead to a focus on milk, a food unavailable in the ancestral environment after weaning (P. Rozin & Pelchat, 1988). The view that adult food preferences are largely formed in the first 6 years of life is a common Western view, perhaps a derivative of Freud's focus on what he designated the critical first 6 years. So far as we know, there is no evidence that the first 6 years are any more important than the next 6, or the next 6 years after that.

Both genetic and early experience accounts predict substantial parent-child correlations in food preferences. However, results from Americans suggest low correlations (averaging .15) between preferences for specific foods between young adult children (college students) and their parents (P. Rozin, 1991). Similar results appear for music preference, while correlations for values, such as attitudes toward abortion, are notably higher (P. Rozin, 1991). Cavalli-Sforza, Feldman, Chen, and Dornbusch (1982) identified three routes for transmission of preferences: vertical (parent-child), horizontal (peer influence), and oblique (e.g., teacher-student, media-child). The low parent-child correlations suggest substantial roles for peers, teachers, heroes, and culturewide forces.

A major cultural difference that probably relates to food preferences has to do with the organization of the household. In traditional cultures, it is common to have three-generation households, with the grandparents playing a substantial role in child rearing. In some respects, modernization, which usually includes participation in out-of-home work by both parents, shifts child rearing, and in particular food shopping and child feeding, more into the domain of the grandparents. In parts of modern urban China, grandmothers seem to be the major food socializing agents (Jingxiong et al., 2007). This may be a force that slows down adjustment of children to the most recent trends in globalization, although peer influences probably overwhelm parental or grandparental conservatism. It is not surprising that parents, peers, and other cultural forces produce certain within-culture commonalities in preferences. What is not at all clear is what produces within-culture differences. We do not understand how food preferences are formed, but exposure is necessary, and in some cases, may be sufficient (reviewed by Birch, Fisher, & Grimm-Thomas, 1996).

Peer influence is an obviously important factor in the development of food preferences, perhaps especially in adolescence, in some cultures. It is

clear that a concatenation of forces, including genetics, parental, and peer influences, result in substantial cultural differences in food likes. Although there are genetic differences with respect to taste and smell, cultural differences in genetics probably are not the major cause of cultural differences (Prescott, 2012).

Of course, there is more to transmission than preference. There are attitudes to food and eating, including their importance in comparison to other activities, and the balance of worries and pleasures about eating. These are different between cultures (e.g., between France and the United States), but they also vary considerably within a culture. Recent ethnographic data suggests that some of the major differences in food attitudes between Americans and Southern Europeans may be traced to differences in the types of interactions that occur around the dinner table (Ochs, Pontecorvo, & Fasulo, 1996). The Italian family eating environment is much more oriented toward the shared pleasure of eating, and less to concerns about food and health, and coaxing children or making bargains to promote healthier eating. This work is a promising beginning for systematic studies of food socialization in a cultural context.

CONCLUSIONS

Food is deeply intertwined with biology, psychology, and culture. There are many universals, and many major culture differences. The cultural differences may be conceived as variations on a theme. Preadaptation of foundational food system features is rampant, both within the food world and extending from the food world to other domains. The food system presents particular challenges and particular opportunities for cultural psychology. The cross-cultural and historical records are good, especially since food is so central in archeology and ethnography. The biological constraints and predispositions are well understood. What we need is for more researchers to take up the challenge of explaining a major part of human life, the center of human sustenance, and a major source of satisfaction.

CHAPTER 18

Learning New Cultures

Processes, Premises, and Policies

**Michael W. Morris, Katrina M. Fincher, and
Krishna Savani**

In this age of globalization, rates of migration across national boundaries are at an all-time high. Hence, more people than ever before—whether exchange students, expatriate employees, economic immigrants, or political refugees—face the task of learning new cultures. We focus in this chapter focuses on how newcomers learn the norms of a culture, particularly the tacit norms of interpersonal interactions. While traditional theory and practice have emphasized the primacy of conscious declarative knowledge, we propose that some kinds of cultural learning begin with procedural knowledge that is often unconscious. To investigate our theory, we outline a dual-process model, in which procedural learning can come first and declarative learning later. We further propose domains and conditions in which this is likely to happen. In addition, we address the age-old question of how internalizing one culture affects competency and fluency in another culture. If people pick up new cultures through procedural learning, fluency in one culture may interfere with fluency in another culture because of processes in procedural learning, such as blocking, state dependence, and priming. Finally, we discuss the applied problem of how to select and prepare people for organizational roles that require intercultural fluency. The role of procedural mechanisms in cultural learning suggests a different approach to the aptitude dimensions for selecting candidates and to training and coaching methods to foster their learning.

Lisa's software company transferred her unit from San Jose to Bangalore a year ago. In her e-mails home, Lisa reports being "too busy meeting deadlines with her coders to learn anything about India." However, when

some former coworkers visit, they notice some definite changes in her style. Lisa has become more patient in dealing with subordinates. In addition, she works more cooperatively with peers. Whereas in California she had protected her time, here in India she drops her own task to help a colleague in need. Although Lisa did not consciously change her habits, she has, in fact, internalized some Indian interpersonal norms. Research has found that Indians, compared to Americans, are more likely to exhibit patience, accommodate requests, and offer help without concern for reciprocity (Miller et al., 2014; Perlow & Weeks, 2002; Savani, Morris, Naidu, Kumar, & Berlia, 2011). With these gradual changes to her operating style, Lisa has become a more effective manager in India than her fellow California transplants, even those who made more effort to study Indian culture. Lisa's style has changed so dramatically that her friends understandably wondered whether, given her new habits, she would struggle to readapt if she came back to work in the United States.

The story of Lisa's adaptation to India challenges the dominant models of second-culture learning or acculturation in cross-cultural psychology (Bhawuk, 1998; Bhawuk, Sakuda, & Munusamy, 2008). These models draw upon classic studies of novices and experts in chess, physics, and other domains (Chase & Simon, 1973). They posit two key stages of expertise development. First, the learner acquires declarative knowledge, such as verbalized if-then rules about what action to choose in a certain situation. These verbalized rules require concentrated effort to recall and to enact. However, if the action is practiced in the relevant situation for a long enough time, the situationally contingent response can become automatized or proceduralized in a second stage of learning. After this happens, the person performs the action in the situation as a habitual reflex, without needing to concentrate on doing so (Anderson, 1982). Howell's (1982) model of intercultural learning elaborates this theory with more colloquial terminology. According to Howell, newcomers must initially acquire "conscious competence"—verbalized understandings of cultural norms that require concentrated effort. Only after repeated practice can newcomers eventually develop "unconscious competence"—retrained associations and reflexive habits that operate automatically. Similarly, Bennett's (1986) stage model of intercultural development proposes that an expatriate must first

reach the stage of consciously recognizing differences in norms and, only later, progress to developing new behavioral and cognitive habits.

These models centering on declarative knowledge not only shaped basic research on cultural learning but also applied practices of cultural training. In the Peace Corps, the Armed Forces, and many corporations, candidates are trained with lectures and guidebooks emphasizing declarative knowledge. Trainings typically feature abstract verbal statements about value orientations (“Latin Americans are collectivistic”) as well as behavioral injunctions, such as “Never pat a Buddhist on the head.” A similar approach is seen in the generalizations and “Dos and don’ts” lists offered in diversity trainings undertaken by hospitals, police forces, and universities for professionals who work with culturally diverse populations (Abbe, Gulick, & Herman, 2008; Crandall, George, Marion, & Davis, 2003; Ward, Landis, & Bhagat, 1996).

For some domains of cultural learning, the standard model and associated training methods work very well. When learning about a country’s currency or cuisine, to name a few examples, novices start by following rules that they learn in a guidebook or cookbook. Only later do learners become able to choose the right bills or add the right ingredients on autopilot while their conscious attention is deployed elsewhere. This competence development works much like that in the domain of chess where this progression from declarative to procedural knowledge was first observed.

However, in other domains of cultural learning, competence may develop in other ways. Consider the tacit norms of interpersonal interactions, the dance steps of social life (Hall, 1983). In our opening example, Lisa developed new ways of interacting with colleagues that she seemed unaware of and certainly could not articulate as verbalized rules. She did not learn them from a guidebook or training session; she picked them up through long days of trial-and-error when interacting closely with locals to finish projects.

It is quite possible that in the domain of interpersonal behaviors, an expatriate might initially exhibit a new behavioral response through the mechanism of mimicry—reflexively mirroring the behavior of locals (Lakin & Chartrand, 2003). Yet mimicry is ephemeral, so the question remains of how such new responses become locked in. The key may be reinforcement:

interpersonal interactions result in outcomes that provide positive or negative reinforcement (Kitayama, Varnum, & Salvador, [Chapter 3](#), this volume). At the simplest level, reinforcement comes from whether or not the interaction succeeds: *Did the colleague agree to your favor request? Did your date accept the invitation to dinner? Did the client agree to the sale?* On another level, reinforcement also comes from positive or negative sanctions delivered by interactants or onlookers: *Did they smile or frown? Did they draw closer or backpedal? Did they offer opportunities and introductions or cut off communication?* Studies indicate that newcomers tend to get rewarded interpersonally when they behave in ways that abide by local norms. For instance, job candidates who adopt the behavioral mannerisms of their foreign recruiters have more success in landing a job (Sanchez-Burks, Bartel, & Blount, 2009). In summary, mimicry is a reflexive mechanism that can induce a newcomer to perform a culturally appropriate action in a situation, and systematic reinforcement can then serve to lock in this new response (or at least increase the likelihood of repeating this response in the situation on future occasions). This is a process for gaining cultural competence without any need of verbalized declarative knowledge.

Lisa's story not only challenges traditional models but it also suggests alternative cognitive mechanisms that likely play a role in learning new cultures. It raises the following intriguing questions:

- Can expatriates pick up cultural norms from interactions through procedural learning without declarative learning?
- What features of interactions enable procedural learning rather than declarative learning?
- What types of individuals are more likely to learn norms procedurally?
- Does procedural learning help explain conflict between first- and second-culture competence?

By considering such questions, our intent is to provide a fresh look at how newcomers learn a culture's interpersonal norms. We advance this goal in three sections. Firstly, we outline a dual-process model in which cultural learning can begin with either explicit declarative knowledge or implicit procedural knowledge. As we have noted, the standard model of cultural learning accords primacy to declarative knowledge and posits that

procedural knowledge only arises later as practiced behaviors become automatized. While declarative knowledge may be primary in some domains of cultural learning, procedural learning may come first in other domains; that is people acquire competence without initial declarative knowledge. This may help to explain intriguing findings in cultural psychology on the tendency of immigrants' and sojourners to pick up implicit tendencies of the host culture (Heine & Lehman, 2004; Kitayama, Duffy, Kawamura, & Larsen, 2003; De Leersnyder, Mesquita, & Kim, 2011). Recent studies from our lab find evidence consistent with the procedural mechanism of reinforcement learning in the way people pick up cultural norms from interpersonal experiences. As we shall see, this way of learning implicitly from experience is especially likely under learning conditions that bedevil explicit rule-based reasoning (Savani, Morris, Fincher, Lu, & Kaufman, 2017).

Secondly, we use the dual-process model to investigate the age-old notion that first- and second-culture fluency can conflict. Interference can occur both ways. It is a familiar idea that deep grounding in one's first culture makes it hard to learn a second culture—one feels “culture shock” at the loss of familiar reference points. Communications researchers have expressed this notion in their claim that immigrants must “unlearn” their heritage culture norms in order to become fluent in the host culture (Gaw, 2000; Gudykunst & Kim, 2003).

A more provocative claim is that second-culture fluency can interfere with first-culture fluency and identification. In our example, Lisa's friends foresee reverse culture-shock—that Lisa will find that her new habits don't mesh when she returns to the United States. Political theorists have long argued (Plato, 360 B.C.E.) that extensive exposure to a foreign culture threatens a citizen's fit and bond to his or her first culture. Decreased adherence to norms as a result of foreign exposure has been documented in recent research (Lu et al., 2017).

But according to the standard model such interference of one cultural competence with another is hard to understand—newly gained declarative knowledge doesn't conflict with previously learned declarative knowledge. However, to the extent that second-culture fluency reflects retrained associations and habits, then it is easier to understand how acquiring a new set of habits can reduce one's fluency in the old set of habits. The procedural-

priming process suggests new ways to understand and transcend conflicts between first- and second-culture competency. To this end, we explore the dynamics of implicit cognition, such as blocking, state-dependent memory, and procedural priming.

Thirdly, in the final part of this chapter, we consider the applied problem of selecting and training personnel for overseas roles. Traditional selection practices focus on aptitudes relevant to declarative learning, and hence have selected personnel based on factual knowledge about the host country and aptitudes, such as IQ, that are relevant to declarative learning. Likewise, cultural and diversity training heavily emphasizes declarative knowledge about cultural differences. Such trainings teach general value orientations and if-then rules about what to do or not to do. We review evidence about which training methods have been found to be effective. Several empirical puzzles in this literature can be seen in a new light from the perspective of procedural learning as primary. The procedural primacy model oversees positions in which interpersonal fluency is paramount, such as sales, service, or spying roles.

PROCESSES: DECLARATIVE AND PROCEDURAL LEARNING MECHANISMS

Rival traditions in psychology have portrayed cognition in terms of associations (Rumelhart & McClelland, 1986; Thorndike, 1908) and rules (Anderson, 1990; Newell & Simon, 1972). In the past decade, however, many theorists have proposed that both camps are correct, that the mind encompasses two qualitatively different systems of cognition. The first, “System 1,” or “intuition,” is nonconscious, automatic, and effortless. It stores knowledge in the form of associations. “System 2,” or “reason,” on the other hand, is conscious, deliberate, and effortful. Unlike System 1, System 2 stores knowledge in the form of verbalized concepts and rules (Kahneman, 2011; Schacter, 1987; Sloman, 1996; Stanovich & West, 2008).

Procedural learning is part of System 1, in that it deals with the formation of habits and skills through the strengthening of stimulus–response associations (Wood & Runger, 2016). Declarative learning is related to System 2, in that it involves the acquisition of rule-like verbalized

representations through studying and reasoning (Fodor & Pylyshyn, 1988). In our evolutionary history, procedural learning was the first form of learning to appear and is shared by many other species. It is also every person's first form of learning, as it begins in the womb (Tulving & Schacter, 1990). Declarative learning marks a later development in evolution, so it is shared by few (if any) other species. It also comes online later in child development. Declarative knowledge can be acquired very quickly through communication, whereas it can take many repeated experiences, through procedural learning, to form stimulus–response associations sufficient to complete a task. That said, procedural learning is long lasting; for instance, even after years of no practice, a person does not forget how to ride a bicycle. Thus, we suggest that both learning mechanisms play a crucial role in cultural learning, depending on the particular domains and conditions. The differing strengths and weaknesses of the two learning mechanisms can predict which mechanism predominates in a given domain of knowledge or under a given set of conditions.

One can acquire a competency through either mechanism or a combination of the two; however, each type of learning comes with its own set of advantages and disadvantages. Consider, for example, the task of memorizing a telephone number. Through mnemonic techniques such as chunking, a person can accomplish this task through declarative learning. Alternatively, he or she could dial the number, get reinforced by success, repeat the process, and eventually form procedural knowledge. As mentioned, each mode of learning presents its advantages. On the one hand, declarative memory enables one to recall and dial the telephone number anywhere as long as one is able to concentrate on the task. Procedural memory, on the other hand, makes the dialing of the number a response that surfaces only in the situation of looking at a telephone keypad. People often struggle to recall even brief PIN codes if they are not looking at a keypad.

When Is Cultural Learning Primarily Declarative?

Standard models of acculturation give primacy to declarative learning. They draw on models of expertise acquisition (Anderson, 1990; Fitts & Posner,

1967), grounded in studies of novices and experts in chess, physics, and other similar domains (Chase & Simon, 1973; Larkin, 1981). According to these models, all learning starts out as declarative knowledge, and procedural knowledge is acquired only later. The learner begins by memorizing verbal rules about the domain, which require concentrated effort to follow. Only after an action in a situation has been repeated many times can it become proceduralized, such that it can be performed reflexively when one's attention is focused on other tasks. Howell (1982) proposed that this sequence applies to the development of expatriates' cultural competence as well, that "conscious competence" must precede "unconscious competence." Similarly, classic models of immigrant acculturation portrayed it as a deliberate matter of following an assimilationist or separatist strategy (Berry, 1990).

But should we expect that all domains of life are learned in the same way? It doesn't look that way in the case of immigrant acculturation. Immigrant children learn host culture ways at dramatically different rates in structured domains, such as classroom comportment, and less structured domains, such as playground interactions with peers (Phinney, Berry, Sam, & Vedder, 2006). New children from foreign cultures often manage quickly to master appropriate classroom behaviors toward their teachers but take longer to become fluent in the ways that their peers socialize. No doubt, this may reflect what they (or their parents) prioritize, but in part it may reflect the structure of the domain. The norms of the classroom may be simpler to encode, as they apply to all students in the same way, and tend to be enforced unambiguously and articulated in verbal rules. In the domain of playground interactions, the regularities are hazier and the feedback is noisier. The norms of the classroom may afford declarative learning to a greater extent than the norms of the playground.

Similarly, expatriates may acquire cultural competence in different domains through different processes. A Brazilian expatriate in Turkey might learn a local religious practice—"If entering a mosque, then remove your shoes"—from a guidebook. If not, he might be instructed verbally by a local on his first visit to a mosque. Rules about a religious setting are relatively easy to learn through declarative processing. Because the situation is visually salient, other people around can be seen following the rule, and they will give you explicit feedback if you violate the rule. The same is true in other

well-structured domains, such as rules of traffic, cuisine, or currency. In such domains, the standard model of declarative learning as a primary step likely applies. But the domain of interpersonal interactions is different, so the model of learning norms first as explicit verbalized rules may not hold when it comes to the tacit interaction rituals of interpersonal activities, such as meeting, flirting, bargaining, mentoring, and so forth.

Declarative learning can take a number of forms. Expatriates and immigrants often begin declarative learning prior to departure—reading guidebooks, history, and novels; sitting in classes and trainings; conversing with people who have lived in the prospective host country. But declarative learning does not end there. Upon arrival, newcomers to a cultural setting inevitably encounter unfamiliar behaviors that puzzle them. These trigger an attributional process akin to how scientists investigate a hypothesis. Newcomers who witness an unexpected behavior may search for an explanation. They may “collect more data” by watching other people in the same situation and checking for a behavioral regularity or consensus. They may “conduct an experiment” and act in the new way in order to see what happens. When self-consciously trying out new behaviors in this way, one is learning from experiential feedback through reasoning about it as evidence, an explicit-cognition mechanism.

A strength of declarative learning is that it doesn't require many episodes of repeated experience. A single experience with a book, lecture, or conversation can impart a rule. And rules can be induced from experienced feedback sometimes after just a few episodes. Also declarative knowledge can be easily communicated. They be encoded into organizational policies, so that one expatriate's insight about local norms can be shared with many fellow employees.

However, declarative learning has sharp limitations in bandwidth. Humans can hold only a few pieces of information simultaneously in our working memory (Cowan, 2010). If a religion's headgear prescriptions did not apply universally but instead depended on the season, setting, age, gender and marital status, the custom would be difficult to acquire via declarative learning. In experiments involving learning from feedback, when participants are tasked with learning a single-cue contingency, they perform better when given ample time for conscious processing. However, when participants have to learn a multiple-cue contingency (which cannot be

easily verbalized), they perform better when put under time pressure and thereby forced to use procedural learning (Maddox, Ashby, Ing, & Pickering, 2004a).

In theory, another advantage of declarative knowledge is generality—one rule can cover many specific situations. General rules, however, tend to be very abstract, and, in practice, abstract rules are challenging to apply to new situations. For example, suppose a person had learned a rule about preserving face in China, such as “Do not refuse a public overture of generosity,” in the context of dinner invitations and applies the rule in this situation. When encountering an invitation in a different social situation, such as an offer to help solve a problem, the person may not recognize it as an overture of generosity and hence may decline the offer, insulting the Chinese host. This is known as the problem of “inert knowledge,” whereby abstract rules learned in one situation are applied in that situation but *not* applied in situations of the same kind that differ in superficial details (Ross & Kilbane, 1997).

Furthermore, acting on the basis of situation–action rules presents a challenge in interpersonal interactions, because interpersonal situations are fleeting events rather than concrete places. In the aforementioned religious norm example, the salient sight of the mosque triggers the application of the if-then rule. In contrast, interpersonal situations are not fixed settings that one can see as one approaches. They are events that unfold around one, often without advance notice. Moreover, mosques or churches are marked by iconic features, such as domes and crosses, which help people to recognize them, whereas different interpersonal interactions such as a favor request or a show of respect don’t have any salient visual identifiers. Instead, they are fuzzy prototypes of a multiplicity of features (Cantor, Mischel, & Schwartz, 1982). Thus, while knowledge in the form of verbalized rules has great cognitive economy, it may be challenging to apply such knowledge in the domain of interpersonal interactions.

In summary, the standard model that competence develops first as declarative knowledge and sometimes eventually becomes proceduralized no doubt applies in well-structured domains like chess, and well-structured domains of culture. However, gaining competence in some domains of a new culture may happen in a different sequence. Newcomers may start learning by developing procedural knowledge and only later, as a result of

reflecting on their behavior, develop declarative knowledge of the behavioral pattern. Whichever way the learning happens (declarative primacy or procedural primacy), the different strengths of the two learning mechanisms complement each other.

When Do People Learn Culture Procedurally?

Increasing evidence suggests that immigrants and expatriates take on host culture patterns that they are not consciously aware of. People who immigrate from Hong Kong to Canada do not only adapt in their conscious behaviors (e.g., using a fork, rather than chopsticks), they also adapt in their spontaneous expressiveness, becoming more extraverted (McCrae, Yik, Trapnell, Bond, & Paulhus, 1998). Adaptation has been observed in implicit emotional and cognitive tendencies. Japanese who move to North America show increased self-esteem, while North Americans who move to Japan become more self-critical (Heine & Lehman, 2004). People's unconscious attentional patterns shift as well; for instance, Japanese sojourners in the United States showed the characteristic American pattern of decontextualized attention after 1 year. Conversely, American students in Japan showed the characteristic Japanese pattern of contextualized attention (Kitayama et al., 2003).

Field studies of sojourners and immigrants have not been able to isolate the mechanism underlying these changes. However, laboratory experiments that manipulate exposure to everyday situations in different cultures find parallel effects. After participants read typical Japanese situations, they exhibit interdependent, self-critical emotions. This happens even for non-Japanese participants who are unaware that the situations came from Japan. In contrast, everyday situations sampled from the United States evoke independent, self-enhancing thoughts and emotions (Kitayama, Markus, Matsumoto, & Norasakkunkit, 1997; Morling, Kitayama, & Miyamoto, 2002). These experiments suggest that exposure to interpersonal situations can instill the cognitive and emotional tendencies characteristic of a culture.

Building on this work, our research group sampled the everyday influence attempts experienced by college students in the United States and in India. The students had to describe their most recent experiences in an

influence situation (Savani et al., 2011). Regardless of whether they were asked about experiences as an influencer or influencee, Indian and U.S. samples differed starkly in their contents and, correspondingly, in the behaviors they evoked. Indian influence attempts were predominantly other-serving gestures, and they evoked accommodation. Conversely, U.S. influence attempts tended to be self-serving, and they evoked resistance. Furthermore, we exposed undergraduates to influence situations from their own culture and from the foreign culture. Across dozens of trials, students had to decide whether to accommodate to the influencer. At the beginning, Indians were much more likely to accommodate, whereas Americans were more likely to resist, consistent with the respective situation ecologies to which they are accustomed. However, as participants were exposed to situations from the foreign culture, their response bias began to shift toward that of the other culture. As a result, Americans became more inclined to accommodate in an ambiguous situation, while Indians became more likely to resist. Reward feedback was not provided in the study, but a measure showed that participants accommodated when they envisioned that it would produce positive outcomes. Thus, the study could not determine precisely how the learning occurred.

Thorndike (1898) first described the mechanism through which stimulus–response associations could be strengthened with positive consequences and repetition. The “law of effect” holds that responses that produce satisfying outcomes become more dominant. The “law of exercise” holds that associations strengthen when rehearsed and atrophy when not rehearsed. In turn, Skinner (1938) found that reinforcement learning was not simply a function of the amount of rewards. Intermittent rewards, such as those provided by slot machines, are fewer in number than steady rewards but highly affecting; they produce learning that extinguishes more slowly. Reinforcement learning can shape behavior even when the feedback is so intermittent or noisy that the learner cannot consciously identify the contingency involved (which response to what stimulus generates the reward).

More recent research focuses on the neural substrates of reinforcement learning, especially on the neurotransmitter dopamine. When the organism experiences a reward, dopamine is released broadly throughout the brain, amplifying the sensitivity of all recently activated synapses to response

signals. In other words, it stamps in or “embrains” the stimulus–response associations (Schultz, 2013; Wise, 2004). Although dopamine signals of various sorts occur in both the midbrain and the prefrontal cortex, they are reward signals only in the anterior striatum (Menegas, Babayan, Uchida, Watabe-Uchida, 2017). Frank, Seeberger, and O’Reilly (2004) found that Parkinson’s patients, who are treated for dopamine deficits, learn less from positive rewards when they are off their medication. The neural mechanism of dopamine broadcasting elucidates why procedural learning has a broad bandwidth: it can take into account many simultaneous cues because all the stimulus–response associations present during the dopamine release get amplified at once. At the same time, it elucidates why procedural learning fails when the reward feedback is delayed. For reinforcement learning, rewards must come immediately, so that the synapses involved are still active and can be stamped in by the dopamine blast. This condition of delay doesn’t undermine declarative learning. For example, you can learn from feedback on a math test even if the feedback comes a week later. But a smile would not work to reinforce an interpersonal gesture if the smile were delivered a week later.

Procedural Learning and Implicit versus Explicit Aptitudes

In order to test the procedural mechanisms of reinforcement learning, we created a paradigm in which participants encounter a series of situations from another culture, in each case choosing an action, then receiving feedback about whether this was the culturally correct behavior (Savani et al., 2017). Feedback of this sort can be drawn upon by either the declarative learning system or the procedural learning system. To test which learning process predominates, we measured individual differences in aptitudes related to the two mechanisms as a way of tracing which mechanism is used.

Some of the most important evidence for the distinction between declarative and procedural learning comes the study of individual differences, in particular, individuals with brain lesion in specific areas relevant to these processes (McGlynn & Schacter, 1989; Mishkin, Malamut, & Bachevalier, 1984; Young, de Haan, & Newcombe, 1990). Amnesiacs have

damage to the medial temporal lobe (MTL) that interferes with forming new declarative knowledge. However, they can form new associations, habits, and skills from repeated practice, such as navigating a floorplan or maze (Knowlton, Ramus, & Squire, 1992; Knowlton, Squire, & Gluck, 1994; Nissen, Willingham, & Hartman, 1989). Similarly, Bechara et al. (1995) found that damage to the MTL hippocampal region is associated with the inability to acquire declarative knowledge about the stimuli experienced in a conditioning experiment. Nevertheless, this did not stop people from acquiring associations to such stimuli. Conversely, damage to the subcortical region of the basal ganglia, specifically the amygdala, is associated with an inability to acquire associations but retention of the ability to acquire declarative knowledge.

In the same way that individual differences in lesions differentially inhibit declarative and procedural processes, individual differences in aptitudes differentially enable them. The declarative mechanism of reasoning about rules and evidence is facilitated by aptitudes related to abstract thinking, such as IQ. Studies of brain morphology confirm IQ's connection to declarative learning, as they show its association with the size and shape of the hippocampus but not of the amygdala (Amat et al., 2008). IQ tests, such as Raven's Progressive Matrices test, assess individual differences in reasoning aptitude (Raven & Court, 1998). Additionally, IQ has been found to predict both performance on many tasks, career success, and even longevity (e.g., F. Schmidt & Hunter, 2004). To the extent that the acquisition of cultural norms from feedback operates through the declarative process of reasoning about rules and evidence, individual differences in analytic abilities such as IQ should predict learning.

By contrast, to the extent that the procedural mechanism of reinforcement learning operates, individual differences in implicit pattern detection should predict learning. The most widely used measure of this is artificial grammar learning task (Reber, 1967, 1969). Participants in the task are shown a series of letter strings and type out each one. For a subsequent surprise test, they are told that there was a pattern in these strings, and they are shown new strings and asked whether each string fits the pattern or not. Participants typically feel that they are just guessing and, indeed, some individuals perform at chance level. However, others perform well above chance, indicating that they implicitly detected the pattern from their

exposure to the original strings. This pattern detection is an elemental cognitive aptitude, a matter of memory and recognition. Strength in this aptitude helps people learn situation–action contingencies, because it helps people identify and remember the relevant situational cues.

Only a few prior studies have compared individual differences in analytic aptitudes and intuitive aptitudes. A study of high school students in England found that students' IQ (as measured by Raven's Progressive Matrices test, the Differential Aptitude Test Verbal Reasoning scale, and the mental rotation test) predicted their performance on standardized math exams better than their implicit aptitude (as assessed through the serial reaction time task; Nissen & Bullemer, 1987). However, the opposite was true—implicit aptitude predicted—for performance on foreign-language exams (Kaufman et al., 2010).

A series of studies in our lab measured both kinds of individual differences (Savani et al., 2017). The outcome measure was the speed with which participants became accurate in choosing the behavior that goes with a given situation. For example, participants were asked to imagine that they were in a new country and had to learn the local greeting rituals through trial-and-error feedback. They encountered many different individuals from the local culture (ranging from 30 to 80 in different studies) and had to choose how to greet each person (e.g., shake hands or bow). After each decision, participants received feedback about whether their decision was culturally appropriate. They had to figure out that it depends on factors such as the gender or the age of the other person. The key dependent measure was the speed with which participants learned the new cultural norms, that is, the increase in participants' accuracy across successive trials. Savani et al. found that participants with higher implicit aptitude (as assessed by the artificial grammar learning task) were faster in learning the new cultural norms, whereas participants' explicit aptitudes (as assessed by a series solution task that is parallel to the artificial grammar learning task but taps IQ) did not predict participants' speed of learning. Thus, this finding is consistent with the idea that people learn the norms of a new culture through a procedural learning mechanism rather than a declarative knowledge mechanism.

In the next set of studies, we tested hypotheses about conditions that theory suggests would particularly favor procedural mechanisms in norm

learning from experiential feedback. We introduced factors to the learning situation known to disrupt explicit declarative processing but not implicit associational processing: when contingency involves a multiplicity of cues, when the reward feedback is fleeting, and when the reward feedback is noisy. Complex contingencies are present in many interpersonal norms (e.g., whether to greet someone by their first name depends on a combination of multiple factors). We conducted an experiment that varied whether the culturally correct action depended on a single cue (e.g., if a man, salute; if a woman, wave) or on multiple cues (e.g., if a man encountered indoors at nighttime, salute; otherwise wave). We found that participants' implicit aptitude was a stronger predictor of learning speed in the multiple-cue condition than in the single-cue condition (Savani et al., 2017). Intriguingly, explicit aptitude negatively predicted learning speed in the multiple-cue condition. The feedback in interpersonal interactions tends to be noisy rather than perfectly reliable, because people often feign positive responses in order to be polite (Reis, 2008). Also, people tend to mask their spontaneous emotions after a brief micro expression, so the feedback received in interactions is often quite fleeting (Ekman & Friesen, 2003). In our laboratory paradigm, we manipulated these aspects of feedback. We provided participants with reliable feedback 100% of the time (e.g., all men in a new culture would respond positively to handshakes and negatively to bows, and vice versa for all women) versus only 75% of the time. In another study, we varied supraliminal versus intraluminal feedback, that is, a smiling or frowning face depicted for 16 milliseconds (with both backward and forward masking) or 416 milliseconds. As expected, learning speed tracked implicit aptitude (indicating a procedural mechanism) especially when feedback was noisy and when it was fleeting (Savani et al., 2017). By contrast, explicit aptitude did not predict learning from noisy feedback and it negatively predicted learning from fleeting feedback.

Conversely, we also investigated a condition predicted to impede implicit procedural mechanisms but not declarative mechanisms to see whether learning, and the predictiveness of implicit aptitude, diminishes. When reward feedback is even slightly delayed, procedural learning breaks down (Maddox, Ashby, & Bohil, 2003). In category learning tasks that require integration of multiple cues, participants cannot verbally articulate the rule, but they still learn to correctly categorize the items through implicit

associational processing of the feedback. In such tasks that require implicit associational mechanisms, even a 5-second delay in feedback disrupts people's ability to learn (Maddox, Bohil, & Ing, 2004b; Foerde & Shohamy, 2011). Thus, in our cultural learning paradigm, we manipulated whether participants received immediate versus delayed feedback. Implicit aptitudes predicted the speed with which participants learned the cultural norm in the presence of immediate feedback. In the case of delayed feedback, participants did not learn the cultural norm on average, and their implicit aptitude did not predict their extent of learning (Savani et al., 2017).

In sum, implicit mechanisms particularly dominate under the conditions of cue complexity, fleeting feedback, and noisy feedback, where explicit mechanisms founder. However, implicit mechanisms cannot operate under the condition of delayed feedback. These findings provide converging evidence for our proposal that people learn the interpersonal norms of a new culture from experiential feedback through implicit associational mechanisms. These results suggest questions for future research about the social settings that evoke implicit and explicit learning mechanisms. From this we can predict the kinds of interpersonal settings where people are most likely to learn implicitly and develop tacit procedural knowledge. Consider, for instance, an expatriate's experience at parties. Such settings present a few kinds of interactions (e.g., greetings) over and over again with many different interactants and the feedback received tends to be noisy and fleeting. Hence, in this setting people will learn from experience through implicit associational processing rather than explicit rule-based processing. Now consider an expatriate conducting negotiations over e-mail. Because e-mail is an asynchronous communication media, others' responses come after a delay rather than immediately. Hence, implicit associational mechanisms cannot operate and learning requires conscious reasoning about other people's positive or negative responses as evidence relevant to hypotheses about unwritten rules of etiquette. If expatriates learn from the experiential feedback of parties and of e-mail negotiations through different mechanisms, this entails that the resulting knowledge would be in a different form. The implicit mechanisms that operate in the setting of parties would produce implicit procedural knowledge. The explicit mechanisms that operate in e-mail negotiations would produce explicit declarative knowledge.

The Role of Metacognition

Metacognition refers to monitoring and control of one's own thought processes (Flavell, 1979). Individuals differ widely in their metacognitive proclivity. These differences are associated with measures of neural functioning, morphology, and connectivity (Fleming & Dolan, 2012). Self-report measures of metacognitive activity predict which individuals are likely to learn better from the same training course (A. Schmidt & Ford, 2003).

A growing body of research shows that metacognitive processes of error monitoring and correction occur implicitly (Frith, 2012). Cultural intelligence theorists have hypothesized that cultural metacognition represents an explicit conscious process (e.g., D. Thomas et al., 2008). However, basic research on cognitive psychology has always posited both explicit and implicit forms of metacognition. Implicit error monitoring is the voice from the gut that tells us we have just locked our keys in the car. Skilled typists slow down after an error, even if they are not looking at their output, which suggests that they are implicitly monitoring their motor errors. In a clever study testing this (Logan & Crump, 2010), a word processor was rigged so that when typists made an error (e.g., typing "tha") the error was autocorrected on the screen (e.g., it appeared as "the"), but their typing speed still slowed down after errors, indicating that error monitoring happens through implicit processes. Their implicit monitoring system detected the error even though their conscious perception did not.

Models of cultural intelligence include a dimension of cultural metacognition, which assesses the extent to which people are aware of, and update, their cultural assumptions as they engage in intercultural interactions (sample item: "I am conscious of the cultural knowledge I apply to cross-cultural interactions"; Ang et al., 2007). Preliminary studies have indicated that metacognitive cultural intelligence scores are correlated with the extent to which people understand and adjust to foreign settings (Ang et al., 2007; Mor, Morris, & Joh, 2013). Metacognitive proclivity also predicts effective collaboration in intercultural working relationships and teams (Chua, Morris, & Mor, 2012; Brett, Behfar, & Kern, 2006). Cultural intelligence theorists have hypothesized that such positive intercultural outcomes arise through a learning advantage. For instance, cultural

metacognition possibly enables expatriates to better learn from their everyday experiences in a foreign cultural setting (Ng, Van Dyne, & Ang, 2009). However, evidence about this learning process has so far remained elusive.

Through our laboratory paradigm for assessing the learning of foreign norms from experiential feedback, we managed to test this important hypothesis. A series of experiments confirmed that participants scoring higher on the cultural metacognition scale (Ang et al., 2007) were faster at learning foreign norms from feedback across multiple trials. In some studies, they learned contingencies of cooperation behaviors from verbally represented interactions. In most of the studies, they learned contingencies of greeting behaviors from visually represented interactions. To make the task of learning greetings more challenging we ran it with noisy feedback.

The experiments also elucidated the metacognitive processes involved. Consistent with an error monitoring mechanism, the link between metacognitive proclivity and learning was mediated by surprise responses. Implicit error monitoring involves confidence judgments that make people less surprised by success feedback and more surprised by (spurious) error feedback after a correct answer. The surprise index showed that the advantage of individuals high on metacognitive proclivity was carried by their more active error monitoring activity during the learning task (M. W. Morris, Savani, & Fincher, in press).

To complement this correlational evidence from individual difference studies, we conducted experiments that manipulated situational prompts for metacognition. Metacognitive prompts are pauses and/or messages that encourage reflective processing about one's performance, often built into computer tutorials (Crook & Beier, 2010; Tanner, 2012; Thillmann, Künsting, Wirth, & Leutner, 2009). One experiment found support for a prediction from the implicit error monitoring mechanism that pauses after errors helped learning more than pauses after accuracy. Another experiment varied the message that came with the pause. One condition was a directed prompt that instructed participants to think explicitly ("Please think—Analyze the Feedback"). The other condition was nondirected; the message with the pause gave no instruction for explicit reasoning ("Please wait—Image Loading Process"). Learning was faster with nondirected prompts than directed prompts, consistent with the role of implicit associational

processing rather than explicit rule-based processing. Overall, these studies find that metacognitive activity, whether from a dispositional proclivity or a situational prompt, helps people learn foreign norms from experiential feedback.

While we have discussed implicit and explicit processing as separate mechanisms, it is important to emphasize that the two processes can work together in a learner's journey toward proficiency in a domain. The standard model of second-culture learning acknowledges this by proposing that initially declarative knowledge becomes proceduralized. Likewise, in domains where individuals learn an situation-action contingency through implicit associational learning, this tacit knowledge may eventually become "declarative-ized" Through reflecting on their behavioral patterns, individuals can become able to articulate the contingency that they have been following implicitly. Whichever form of knowledge comes first, it can spawn the other kind of knowledge. The two kinds of knowledge work together to regulate and guide behavior. Also, as Bandura (1989, 2001) reminds us, experiential learning of the type we studied is often preceded and complemented by vicarious learning, watching others in the situation and observing how their actions get rewarded. Vicarious learning, likewise, can operate implicitly or explicitly, and the two forms can work in combination just as in experiential learning.

PREMISES: REPLACEMENT VIEW VERSUS SUPPLEMENT VIEW

The question of whether learning a second culture changes one's proficiency in one's first culture has been an age-old debate. According to the replacement view, when a person acquires competence in a new culture, such fluency conflicts, to a greater or lesser degree and for at least some time, with the person's native-culture fluency. In contrast, the supplement view, which has been more dominant in acculturation research, considers that the gain of second-culture proficiency leaves one's native-culture competence undiminished and, perhaps, even enhanced.

The replacement view underlies the age-old anxiety that exposure to a foreign culture may be corrupting. For example, in 360 B.C.E., Plato

recommended that states should not allow ordinary citizens to have contact with foreign visitors. The fear was that citizens would embrace the foreign ways and lose touch with their domestic customs. Plato advised that foreign travel be restricted to citizens above the age of 40, presumably because they are less susceptible to learning new and different norms of behavior. Through history regimes have restricted immigration and foreign travel; ancient Mesopotamia (in its Hammurabi code), Japan (in the Sakoku Edict), and the contemporary hermit kingdom of North Korea. Some classical arguments about acculturation, such as that two cultures in contact inevitably change each other is also influenced by the replacement view. Similarly, the replacement view gave rise to the idea that migrants assimilate in a “straight line”; that is, that they increasingly fuse with the mainstream and, with each generation, gradually disconnect from their heritage culture and community (Gans, 1973; Herskovits, 1938).

Furthermore, the cross-cultural psychologists Gudykunst and Kim (2003) made the controversial claim that learning a second culture may require that the person “unlearn” his or her native culture. It is important to determine what is meant here by “unlearn.” If it means forgetting declarative knowledge, that would seem unnecessary as knowing one set of rules doesn’t inhibit learning a new set of rules. However, if to unlearn means to extinguish an automatic association or habit, then it makes more sense, as one pattern of associations can interfere with another. Consider the difficulties that foreign students from Korea encounter when they come to the United States for law school or business school. Acting deferentially in front of teachers and maintaining harmony in groups has been inculcated into them since childhood. But in the American classroom they are supposed to ask challenging questions of the teacher and debate points made by fellow students. They know consciously what they are supposed to do in order to get a good class participation score, but they find it difficult to master it in practice and make it habitual. Even if they are fluent in English, their Korean norms of deference get in the way of adapting to the American norms of debate.

The interference between Korean and American cultural competencies would not be happening if they solely involved declarative knowledge. The Korean students have no trouble gaining conscious declarative knowledge about the expectations of classroom participation. However, if we accept

that such competencies comprise trained stimulus–response associations and habits, it becomes easier to understand the conflict or interference. For example, interference in learning a second culture may result from blocking effects. In the case of blocking, the conditioning of a response to a stimulus is impaired when presented together with a second conditioned stimulus that is already associated with the response (Kamin, 1969; Blaisdell, Gunther, & Miller, 1999). For instance, Korean students may find it hard to pick up when the professor signals that student questions should end, as the mere presence of the professor already cues that response.

Even so, the conflicts that newcomers experience while learning a host culture are not permanent. Researchers have long observed that some immigrants become fluent in and engaged with the host culture without losing attachments to their heritage culture. For example, W. Thomas and Znaniecki (1918) studied Polish immigrants in Chicago and noted three acculturation patterns: The first type embraced the host culture and abandoned their heritage culture. The second type rejected the host culture and adhered to their culture of origin. Finally, the third type engaged with the host culture while also maintaining significant heritage–culture identity. Drawing on these ideas, Berry (1974, 1990) developed a self-report scale that categorizes immigrants into four acculturation strategies: assimilation, separation, integration, and marginalization. “Assimilation” denotes engagement with the host but not the heritage culture. “Separation” entails engagement with the heritage but not the host culture. “Integration” involves engagement with both cultures. Finally, “marginalization” denotes the absence of engagement with either culture. Berry (1990) predicted, and found, that integration was associated with the highest levels of psychological adjustment. To summarize, the research on immigrants has shown that second-culture proficiency does not always crowd out first-culture proficiency. In addition, studies have indicated that second-culture attachments can balance, rather than displace, first-culture attachments.

The integrated acculturation strategy does not imply that immigrants develop habits that blend heritage–culture and host–culture patterns. Rather than having one mode of behavior that falls in between the two cultural prototypes, bicultural individuals have two modes of behavior. They switch from one cultural response mode to another, depending on cues in the situation (Benet-Martínez, Leu, Lee, & Morris, 2002; Hong, Morris, Chiu, &

Benet-Martínez, 2000). The question we ask is, how do they manage their dual cultural competencies? For instance, if German and Turkish norms about how to respond to an insult diverge, how does a Turkish German, who moves between the two communities, manage respond appropriately? How do they avoid exhibiting a Turkish reflex in a German setting, or vice versa? One of the helpful characteristics of both procedural learning and declarative learning in this case is context dependence. For the German–Turkish bicultural person, the surrounding cultural context, such as familiar sounds, smells, and sights of a cultural setting, serves to prime the cultural cue for the enactment of Turkish or German norms, whether consciously or nonconsciously.

Certain artifacts, landmarks, and historical figures are so highly associated with a cultural tradition that they may be called icons. When bicultural person observes iconic symbols, such as a the dome of a mosque or the cross atop a church, this automatically elevates the accessibility of the declarative and procedural knowledge associated with the corresponding culture. As a result, its concepts and scripts are likely to activate and guide the person's information processing, which results in thoughts and behaviors that adhere to the norms of that culture (Fu, Chiu, Morris, & Young, 2007; Hong, et al, 2000). Priming is thought to underlie biculturals' capacity to frame-switch from cultural mode to another. This occurs when they move from heritage situations to host–culture situations, and vice versa.

Nevertheless, any automatic process sometimes go haywire. In order to explore potential cases in which cultural priming impedes performance, Zhang, Morris, Cheng, and Yap (2013) studied newly arrived Chinese immigrants in the United States and tested whether the immigrants' fluency in English was disrupted when primed with visual cues to Chinese culture. In a simulated teleconference conversation conducted in English, Chinese immigrants spoke less fluently when their ostensible interactant had a Chinese face, rather than a European American one. This occurred despite the fact that the immigrants reported greater social comfort with the Chinese interactant. Another study replicated this effect; instead of faces, however, it used images of Chinese landmarks, such as The Great Wall, as opposed to American images, such as Mount Rushmore. In other studies, after their exposure to Chinese images, Chinese immigrants were more likely to use literal translations from Chinese in an object-naming task. For

instance, they called pistachios “happy nuts.” In a further study, the Chinese participants recognized these anomalous phrases faster after looking at Chinese images rather than American ones, indicating that these phrases had elevated accessibility in their minds.

In culturally mixed environments, visual cues to a person’s heritage culture may interfere with the person’s attempts to fluently enact the host culture. Birman, Trickett, and Buchanan (2005) compared adolescents’ acculturation in two communities of Russian immigrants living in the same state in the United States. In one of the communities, the Russians lived in a concentrated ethnic enclave. In the other, the people lived dispersed throughout the area’s multicultural neighborhoods. American acculturation and Russian culture retention was measured in terms of linguistic fluency and consumption behavior related to media, music, food, and entertainment. It was also measured in terms of identification, as expressed by views such as “I consider myself American” and “I consider myself Russian.” Time spent in the United States positively predicted measures of U.S. acculturation in terms of language, behavior, and identification. At the same time, it negatively predicted Russian language and interpersonal behavior, but not identification. (This may reflect that language and interpersonal behavior are carried by implicit procedural knowledge whereas identification is carried by explicit declarative knowledge.)

Interestingly, time spent in United States also interacted with the type of community in which the immigrants lived. The relationship between time spent in the United States and U.S. linguistic, behavioral, and identity acculturation was stronger in the dispersed community, which suggests a faster process of acculturation. Less frequent social interactions with fellow Russians most likely meant less priming and reinforcement of Russian habits. To summarize, interference between host- and heritage culture fluency may arise out of both heritage–culture habits and accessibility of these habits.

There are reasons to believe that different types of norms follow different patterns of learning. Specifically, more affectively laden cultural norms may be more difficult to change than cultural norms that are affectively neutral. For instance, American immigrants acculturate to political and economic practices, such as voting and maintaining savings accounts, faster than they acculturate to religious and parenting practices (Glazer & Moynihan, 1963;

Navas et al., 2005). Similarly, Hong Kong, a society that combines Chinese ethnicity and Western institutions, teaches schoolchildren about role models drawn from both Eastern and Western history. However, it is only in some domains of learning that the role models are drawn from both Eastern and Western history—the role models in instrumental domains are largely comprised of Westerners such as Thomas Edison, while role models in the moral domains tend to be exclusively Chinese (Fu & Chiu, 2007).

These results are consistent with studies according to which moral norms are distinct from other types of norms in several aspects (Turiel, 1983). People cognitively treat moral rules much in the way that they do scientific facts (Goodwin & Darley, 2008). Hence, moral norms are likely to be primarily represented as declarative knowledge. They do not seem to be conditioned habits that are triggered only in certain situations. Such loyalty may also indicate that learning a second culture would not change a person's tendency to adhere to the moral norms of his or her native culture. For example, although Saudis who eat mutton in Saudi Arabia may adapt to beef in the United States, they might have a more difficult time adapting to norms in moral domains, such as gender equality.

POLICIES: PROMOTING CROSS-CULTURAL COMPETENCE

The United States, like many other countries, faces challenges of globalization in the areas of commerce, civic society, and the military. The absence of linguistically and culturally flexible employees in business puts the country at a disadvantage in competitive global industries, a loss estimated in the billions every year. Likewise, U.S. law enforcement, education, and health care systems struggle with the challenges of cultural diversity in our communities. Ethnic minorities constitute half of the population in California, Hawaii, New Mexico, and Texas. By 2050, it is predicted that they will amount to half of the nation's population. In Iraq and Afghanistan, the Army's shortage of competent translators and cultural expertise led to substitutes that would be considered comic had their results not been so tragic. Soldiers were issued wallet-sized "smart cards" with some basics about Iraqi customs and phrases. When that proved insufficient, they

developed a handheld device, the “Phraselator,” which, via pushing buttons, emitted phrases in Arabic and in other languages. Among such phrases were “Not a step further,” “Put your hands on the wall,” and “Everyone stop talking.” However, the device did not have the capacity to understand locals’ replies (Mackey, 2004). Additional devices are currently being developed (e.g., Huhns, Vidal, Ruvinsky, Mendoza, & Langevin, 2006). While mechanized cultural expertise may help to bridge unexpected gaps, it also potentially sends a meta-message of disinterest in learning the local culture. Hence, human competence in the local culture would be a better solution.

Organizations like the Army and the Peace Corps that send their members overseas grapple with two practical questions. The first relates to selection; namely, what measurable characteristics predict who will be more able to learn a new culture? The second relates to training; what is the best way to prepare an employee in advance or accelerate their learning from experience once arrived.

Selection

Large applied literatures on expatriate managers and exchange students search for predictors of success. As it is difficult to measure cultural learning per se (see Meziyas & Scandura, 2005), studies of expatriate outcomes measure more general outcomes such as cultural adjustment and work/school effectiveness. While these general outcomes reflect host–culture learning, they also reflect other processes as well. In a valuable review, Ward, Bochner and Furnham (2001) noted that acculturation is studied in three different ways that emphasize different parts of the process: cultural learning, stress and coping, and social identification. The most widely used criterion variable is cultural adjustment, which measures the degree of a person’s comfort in various domains of the host culture (Black, Mendenhall, & Oddou, 1991). It has been found that cultural adjustment hinges on both the expatriate’s environment (e.g., cultural distance, family adjustment, and organizational support) and the individual (e.g., the expatriate’s personality traits and social competences).

The selection of students or employees for overseas roles is contingent on individual factors that can be assessed prior to departure. Organizations

such as the Foreign Service and the Central Intelligence Agency (CIA) have long relied on tests of intellectual aptitude and declarative knowledge about the host country and its language (Rositzke, 1977). However, field studies have found that expatriate managers' IQ do not predict their intercultural adjustment (e.g., Ward, Fischer, Lam, & Hall, 2009). Our laboratory tests of experiential learning of foreign norms mirror this finding (Savani et al., 2017). An additional surprising discovery is that greater knowledge of the host country language is associated with better interpersonal socialization but not general life adjustment or work adjustment (Shaffer, Harrison, & Gilley, 1999). The evidence suggests that aptitude for explicit reasoning and declarative knowledge about the host culture are less sufficient drivers of adjustment than organizations have assumed.

At the same time, studies of expatriate adjustment have found consistent evidence for the predictiveness of other individual differences, so-called "noncognitive" factors. Regarding personality dimensions, Mol, Born, Willemsen, and van der Molen (2005) found that *Conscientiousness* and *Extraversion* predict job performance and work adjustment, while *Agreeableness*, or social flexibility, predicts better interpersonal adjustment. By contrast, *Emotional Instability*, or reactivity, negatively predicts adjustment, both interpersonal and work-related. *Openness to Experience*, or curiosity versus the comfort with routine, predicts both work adjustment and job performance.

The question of *how* exactly these noncognitive personal factors shape expatriate adjustment remains unclear. *Conscientiousness*, *Extraversion*, and *Agreeableness*, as well as low *Emotional Instability*, push people toward engagement with various aspects of life and may therefore be correlated with a higher degree of learning. Alternatively, the observed correlations between the personality dimensions and adjustment may reflect effects of the personality dimensions on expatriates' stress levels rather than their ability to learn. Also, the positive effects of *Openness to Experience* likely reflect general learning rather than culture-specific learning, as this dimension correlates with many different kinds of learning.

While *Openness* is associated with reading and intellectual activities that yield declarative knowledge, it may also relate to procedural learning. Past studies have found that *Openness* is associated with implicit processing aptitude (Kaufman et al., 2010). One possible explanation is that this factor

involves a wider focus of attention or greater interest in patterns. Kaufman et al. further found that implicit aptitudes were correlated with an overlapping personality measure, *Intuition*. Prior studies similarly found individual differences in intuition to be correlated with implicit aptitudes (Woolhouse & Bayne, 2000). This indicates that the “noncognitive” dimensions of individual difference may actually be cognitive in their consequences. These dimensions may underlie implicit cognition and procedural learning, even if they do not correlate with explicit cognition or declarative learning.

Training

In addition to selecting the right people for expatriate roles, organizations strive to accelerate their adjustment through training. Over the past 50 years, researchers and practitioners have developed training methods and tested their efficacy (Black & Mendenhall, 1990; Littrell, Salas, Hess, Paley, & Reidel, 2006). A recent meta-analysis revealed positive correlations between training, on the one hand, and intercultural adjustment ($\rho = .12$; $p < .05$) and performance ($\rho = .23$; $p < .05$), on the other (M. A. Morris & Robie, 2001). Most training programs focus on declarative knowledge—the history, legal system, and social identities in culture. Thus, such lessons emphasize declarative knowledge. We suggest that by considering the differing roles of explicit declarative learning and implicit procedural learning mechanisms, current findings may be understood and current practices improved.

Declarative Knowledge

One of the most common forms of cultural training today is the presentation of abstract findings from cross-cultural research, such as differences across countries in value orientations (Hofstede, 2001; Schwartz, 1994). Cross-cultural psychology has held values to be the essence of culture. However this equation is increasingly questioned (M. W. Morris, 2014; Leung & Morris, 2015). Critiques have been based on the evidence of limited value consensus within countries (Fischer & Schwartz, 2011) and low predictiveness of values relative to perceived norms in many domains

(Vauclair & Fischer, 2011; Vauclair et al., 2015). Regardless of the extent to which values drive a society's characteristic cultural tendencies, whether expatriates and immigrants must take on those values in order to adapt or adjust is another question altogether. Ward and Searle (1991) found that the value discrepancies of international students in New Zealand did not predict their level of sociocultural adaptation. Furthermore, Kurman and Ronen-Eilon (2004) looked at the degree to which immigrants in Israel matched native Israelis in values or in social worldviews (Leung et al., 2002). They found social worldviews to be more important and concluded: "Values may help in understanding a culture, but they have less to do with concrete, mundane behaviors" (Kurman & Ronen-Eilon, 2004, p. 203).

In fact, training people about intercountry value differences may actually have negative consequences. One of the goals of cross-cultural research is to supplant popular stereotypes with "sophisticated stereotypes" (Osland & Bird, 2000). Stereotypes represent rule-like beliefs about social categories that exaggerate differences and thereby simplify, as well as organize, the world (Brewer, 1988). Lessons about cultural differences have the effect of legitimizing generalizations about cultural groups. For example, essentialist beliefs about culture increased among students who took a cultural psychology class (Fischer, 2011). One study found that students in cultural psychology class gained relative to a control group in cultural metacognition, but students with relatively low grades in the class increased their endorsement of erroneous cultural stereotypes (Buchtel, 2014).

The cultural assimilator method is a long-standing training method that imparts declarative knowledge. It trains newcomers to make culturally appropriate attributions for behavior by locals that are often puzzling to newly arrived foreigners (Fiedler, Mitchell & Triandis, 1971). This method was developed by first asking American expatriates to describe interactions with locals that illustrated a cultural clash. The themes in these "critical incidents" were then distilled into a set of prototypical scenarios of confusing behaviors by locals, along with multiple-choice options of explanations for locals' behaviors. One of these explanations was endorsed by locals, while the others were based on cultural stereotypes or misplaced American assumptions. Despite its widespread use, assimilator training has limited evidence of efficacy. It has helped expatriates improve in tests of the attributions they are designed to correct, but it has not improved the

behavioral or emotional aspects of adjustment (Bhawuk, 1998). Originally the assimilators were country-specific; eventually, the similarity in their content led to the development of a culture-general assimilator that presents trainees with 100 critical incidents covering 18 themes (Brislin, 1986). This general tool was found to be as effective as country-specific tools (Cushner, 1989). This finding suggests that rather than teaching the specifics of another culture, assimilators primarily train the learner not to project his or her own cultural patterns onto any other culture. Yet even the best students have trouble remembering 18 distinct lessons. Recent versions that target only a few themes, rooted in theories of individualism and collectivism, have proved superior in retraining attributions (Bhawuk & Brislin, 2000).

Procedural Knowledge

Another tradition of cultural training focuses on learning to perform host-culture practices rather than on learning abstract values and attributions (Harrison, 1992). Influenced by Argyle's (1969) work on the role of social skills in interpersonal interactions, the approach views adaptation as a process in which one learns a repertoire of culture-specific behaviors needed to negotiate interpersonal encounters in a cultural milieu (Bochner, 1972; Furnham & Bochner, 1982). Some of this research has focused on communication styles, including nonverbal communication, such as appropriate gaze patterns, postures, and facial expressions. (Gudykunst & Kim, 1984; Hammer, Gudykunst & Wiseman, 1978; Ward & Kennedy, 1999). The latter fluency also includes the situation-appropriate performance of ritualized routines such as greetings and partings. These interaction rituals play a critical role in the negotiation of relationships (M. W. Morris & Keltner, 2000). Culturally congruent nonverbal behaviors are more powerful than ethnicity in predicting interpersonal attraction (Dew & Ward, 1993). In fact, immigrants who are linguistically fluent but not fluent in the nonverbal norms of the host culture may face particularly unfavorable outcomes (Molinsky, 2005).

One training method that can foster procedural learning is behavioral modeling. For instance, a behavior modification program named Excell (Mak, Barker, Logan, & Millman, 1999), which is based on social learning

theory (Bandura, 1989), aims to instill culturally appropriate actions needed to negotiate everyday encounters, such as initiating contact, entering group discussions, and expressing disagreement. Each skill is initially modeled by an instructor, often someone with theater training. Subsequently, the trainees practice the skills repeatedly while receiving feedback, which includes proxemics, gestures, phrases, intonation and cadence, and suppressing heritage–culture habits. A six-session course has been found to improve social efficacy and social interaction skills (Mak & Buckingham, 2007). Unfortunately, such a course requires the availability of highly skilled trainers. Parts of the course, however, can be replicated with automated tools on smartphones, via the Internet, and on devices such as Nintendo Wii, which use sensors, and face and voice recognition (Lane et al., 2008; for a review, see Laarmarti, Eid & Saddik, 2014).

While behavioral modification engages procedural learning mechanisms to some extent, other methods have shown even greater potential. Among them are experiential methods, such as field visits to the host culture or realistic simulations of the host culture (Brislin & Yoshida, 1994). While visits to a far-away country may be prohibitively expensive, visits to local immigrant neighborhoods may offer similar value as long as the participant is required to behave according to local norms, which is not always the case. Another approach is to establish working relationships, such as long-distance Skype collaborations, with host-country nationals. Expatriate adjustment literature has long found that interpersonal adjustment is associated with sufficient contact with locals (Ward & Searle, 1991) and friendships with them (Furnham & Bochner, 1982). Furnham and Bochner proposed that the best predictor of the cultural learning speed is the number of host-culture friends, as assessed by a network survey. No doubt part of why more relationships and interactions with locals helps is the experiential feedback that conditions the expatriate to local interpersonal norms.

Simulations present another way to receive the experiential feedback needed for procedural learning. The U.S. armed forces have long used interpersonal simulation games, similar to the way they use war games to teach artillery tactics. In traditional simulation, trained confederates play the trainee's counterparts in an intercultural interaction, then provide feedback (Mendenhall et al., 2004; Raybourn, 2007). While the game-like structure makes learning more enjoyable, it is limited to only a few trials. In

addition, the feedback represents an extensive verbal debrief rather than a clear reward; therefore, it engages declarative learning rather than the longer lasting procedural learning, as brief feedback engages the implicit learning system, whereas detailed feedback engages in the explicit learning system (Maddox, Love, Glass, & Filoteo, 2008). Recently, the Army commissioned an interactive virtual simulation to train culturally appropriate behavior (Johnson, Vilhjalmsson, & Marsella, 2005; Johnson, 2007). The players “explore an Iraqi village, hear the sounds, speak to locals, and make gestures” (Lane, 2007, p. 3). Feedback about the person’s behavior arises organically from the responses of the avatars, such as the avatars’ facial expressions and actions. Feedback also comes in the more artificial form of a disembodied voice that gives corrective advice. Such a voice resembles an omniscient sergeant looking over the trainee’s shoulder. While these forms of feedback may seem well designed, they engage declarative rather than procedural learning. If the goal is to impart specific competencies as habits, our studies suggest that the key to learning is accuracy feedback across many trials, as opposed to verbalized explanations.

To summarize, most cultural training has predominantly focused on declarative learning, in part because it’s efficient to deliver. Several methods that engage procedural learning, such as behavioral modeling and experiential education, have been developed and tried by organizations with ample training budgets at their disposal. That said, such methods have not been deployed widely as they are too costly in terms of time and resources. However, new methods have become available through communications and game technologies. Skype interactions with trainers from the host culture may be a good way to instill some important basic competencies. Our findings suggest that procedural learning could be instilled efficiently in first-person simulation games that present repeated examples of types of situations that must be mastered.

Summary

We reevaluate in this final section the long-standing literatures relevant to the selection and training for intercultural roles. Expatriate adjustment studies have identified individual-difference antecedents that might be used

for selection. However, cultural learning has remained an unmeasured black box in between the measured antecedents, such as personality traits, and aptitudes and general measures of outcome, such as cultural adjustment. The surprising lack of importance of IQ and, conversely, the importance of personality factors such as Openness, can be better understood when we consider the role of procedural learning. We suggest that assessors should focus on implicit abilities, metacognition, and related personality variables, such as Openness and Intuition, when they select people for intercultural roles that require intercultural expertise.

In the training literature, the predominant focus has been on declarative learning. Methods that target procedural learning have been dismissed as too resource-intensive. However, our analysis suggests that new technologies make the new variations of these tools more accessible. As future research on procedural versus declarative mechanisms involved in cultural learning seems promising, increased clarity on how these mechanisms work in different domains of learning can be expected. In light of these, better tailored instruments for assessment and tools for training can then be developed.

CONCLUSION

We have addressed in this chapter the question of how people become competent in a new culture. Past theories and practices have emphasized the primacy of declarative learning—that conscious competence precedes unconscious competence. However, we have argued for the primacy of procedural learning in domains such as the norms of interpersonal interactions. We then outlined a dual-process model that distinguishes two sequences—one in which declarative learning comes first, the other in which procedural learning comes first. We have proposed that these two processes of learning operate in different domains of cultural knowledge and under different task conditions. We reviewed evidence that implicit aptitude plays a larger role in helping people learn the norms of a new culture than explicit aptitude, particularly under conditions that challenge the limitations of conscious reasoning, such as multiplicity of cues, fleetingness of feedback, or noisiness of feedback. We have explored how this new model lends

credibility to the age-old premise that competence in one culture can interfere with that in another. Finally, we traced implications for applied organizational policies relevant to selection and training of personnel for roles in other cultures.

CHAPTER 19

The Cultural Psychology of Acculturation

**Batja Mesquita, Jozefien De Leersnyder, and
Alba Jasini**

This chapter lays the groundwork for a cultural-psychological perspective on acculturation. We propose that acculturation is just another example of the mutual constitution of culture and psyche. When people have new cultural experiences, these may not only change how they feel and think *about* their new or heritage culture (explicit affiliation) but also align their thinking, feeling, and acting with the demands of the new cultural environment. To date, most research on acculturation has focused on the former: immigrant minorities' attitudes and identities that *explicitly* endorsed affiliations with their heritage and majority cultural context. Yet an emerging line of research documents how acculturation affects emotion, personality, and other psychological processes that reflect minorities' cultural affiliations more *implicitly*. Reviewing both explicit and implicit acculturation studies through a cultural lense, we outline the important role of the sociocultural context in shaping both the nature and the outcomes of minorities' acculturative changes. In closing, we set an agenda for how future research may advance our cultural-psychological understanding of acculturation.

Exposure to another culture is an everyday reality for first-generation immigrants, but even second and later-generation minorities navigate between the heritage and the mainstream culture in their everyday lives.¹ In this chapter, we discuss the psychological consequences of having sustained contact with another culture, a process that has been termed “psychological

acculturation” (Berry, 1980; Berry & Sam, 1997; Graves, 1967). We suggest that acculturation may pertain to a range of different phenomena, going from simple likes and dislikes (e.g., getting used to spicy food or raw fish), to changes in self-definition (e.g., considering oneself a member of the new majority culture) and “deep” psychological processes such as emotion and personality. Acculturation is a key psychological process in increasingly diverse societies, where a substantial proportion of members of the population either migrated themselves or grew up in immigrant families (e.g., the percentage of immigrants is over 20% of the Western European, 36% of the Northern American, and 48% of the Australian population; Australian Bureau of Statistics, 2016; Humes, Jones, & Ramirez, 2010; Khoo, McDonald, Giorgas, & Birrell, 2002).

An important reason to study psychological acculturation is that it is thought to play an important role in producing health and well-being for minorities. Immigration, and the ensuing adjustment to a new culture, is stressful. However, there are large individual and group differences in the costs of immigration to minority members, and these cannot be explained by structural and economic factors alone (Corral & Landrine, 2008). Psychological acculturation has the potential to explain individual and group differences in immigrant minorities’ healthy adjustment and may therefore provide leverage for intervention (Baysu & de Valk, 2012; Berry & Sam, 1997; LaFromboise, Coleman, & Gerton, 1993; Levecque, Lodewyckx, & Vranken, 2007; Myers & Rodriguez, 2003; Organista, Organista, & Kurasaki, 2002; Suárez-Orozco & Suárez-Orozco, 2001; Yu, Huang, Schwalberg, Overpeck, & Kogan, 2003).

In this chapter, we develop a cultural-psychological perspective on acculturation. We build on the finding that culture “wires” individuals who engage in the local meanings and practices in ways that equip them for the central cultural tasks (Kitayama, Park, Sevincer, Karasawa, & Uskul, 2009; Kitayama & Uskul, 2011); we propose that acculturation is a (partial) rewiring that equips immigrant minority individuals to perform central tasks in the new culture. After outlining this cultural psychology approach in more detail, we first synthesize older research on acculturation, concerned mostly with identity and explicit cultural affiliation, and examine it through a cultural psychology lense. We then review newer cultural-psychological research suggesting that immigrant minorities’ participation

in a new culture also produces effects on such “deep” psychological processes as emotions and personalities; we refer to these effects as “implicit acculturation.” We conclude by outlining future directions of a psychology of acculturation that includes both explicit and implicit domains of acculturation.

A CULTURAL-PSYCHOLOGICAL APPROACH TO ACCULTURATION

A tacit assumption of much acculturation research has been that while cultural affiliation and identity of minorities change, the “psyche itself” remains untouched. Thus, acculturation research has focused on the attitudes *about* the new (heritage) culture, the motivation *to be part of the new (old) culture*, feelings *about* being displaced, and cognitions *about* the new rules of engagement. However, changes in self-concept, motivational, emotional, and cognitive processes themselves have received little or no attention (but see the literature on frame switching; e.g., Hong, Morris, Chiu, & Benet-Martínez, 2000; Pouliasi & Verkuyten, 2007). Another case in point is language learning, which has been treated as a competency rather than as the psychological transformation it is likely to be (Pavlenko, 2014).

In this chapter, we adopt a cultural-psychological perspective on acculturation, and propose that new cultural experiences have the potential to deeply change the psyche beyond how people feel and think *about* the new (or heritage) culture (see also Cresswell, 2009; De Leersnyder, 2014; Mahalingam, 2006). In taking a cultural-psychological perspective on acculturation, we conceive of acculturation as an instance of the mutual constitution of culture and psyche. We propose that mutual constitution continues into adulthood, and does not stop after socialization in childhood. The engagement of individuals in everyday cultural routines, social interactions, and institutions continues to shape their psyches (Boiger, De Deyne, & Mesquita, 2014a; D’Andrade & Strauss, 1992; Fiske, Kitayama, Markus, & Nisbett, 1998; Markus & Hamedani, 2007; Markus & Kitayama, 1991b; Markus & Kitayama, 2003; Mesquita, 2003; Shweder, 1991). Acculturation, then, is the (partial) alignment of a wide range of psychological processes to the requirements of the *new* culture’s everyday

routines, social interactions, and institutions. Engaging in the new culture's practices adds new experiences to existing ones, thereby shaping the psyche; these new experiences are likely to change but not completely override previous experience. In that sense, the process is better thought of as *adding new wiring*, rather than *rewiring*.

By taking a cultural-psychological approach, we hope to advance acculturation research in several different ways. First, a cultural-psychological approach extends the range of psychological phenomena to be studied in acculturation research. It suggests that there may be changes in psychological processes, in addition to changes in the ways in which immigrant minorities explicitly position themselves toward the new mainstream and heritage culture. Thus, in addition to the commonly studied processes of acculturation attitudes and cultural identification (e.g., Benet-Martínez & Hong, 2014; Berry, 1974, 1980; Berry, Phinney, Sam, & Vedder, 2006b; W. Lee & Tse, 1994; Phalet & Schönplflug, 2001; Phinney, 2000; Phinney, Horenczyk, Liebkind, & Vedder, 2001; Phinney & Ong, 2007; Schwartz, Unger, Zamboanga, & Szapocznik, 2010), experiences in the majority culture may lead to changes in emotions, personality traits, self-esteem, and cognition that do not have cultural belonging as their object (e.g., De Leersnyder, 2014; De Leersnyder, Mesquita, & Kim, 2011; Güngör et al., 2013; Heine & Lehman, 2004; Savani, Morris, Naidu, Kumar, & Berlia, 2011).

Second, a cultural-psychological approach focuses on the role of context in acculturation. We are not the first to point out the significant role of context. Research has shown that society-level ideology and intergroup relations shape immigrant minorities' acculturation strategies and cultural identification (Berry, 1974, 2006; Berry et al., 2006b; Bourhis, Moise, Perreault, & Senecal, 1997; Brown & Zagefka, 2011). We discuss this research in the next section on acculturation in explicit domains. The important role of context has also been shown in research with biculturals. This research has found that biculturals selectively adopt acculturation strategies and change cultural identification to match the culture that is foregrounded within a given situation (e.g., Arends-Tóth & van de Vijver, 2004; Doucerain, Dere, & Ryder, 2013; Phalet, van Lotringen, & Entzinger, 2000). Whereas acculturation research before our own has included culture and context as significant factors in acculturation, foregrounding the role of

context, as we do in this chapter, leads to a more systematic questioning of the role of culture in the research findings than has been commonly found in the literature.

Taking the first two extensions together, we suggest that individuals who engage in a new cultural context also undergo psychological changes that are not *about* the majority or heritage culture—*acculturation in implicit domains*. We assume that this implicit acculturation occurs when psychological changes allow minority individuals to better accomplish the central cultural tasks in the majority culture (Kitayama et al., 2009). Thus minority individuals undergo psychological changes that equip them to successfully navigate the majority culture in which they participate. This idea is compatible with the finding of cultural frame switching—defined as the “tendency to fluidly move between different cultural frameworks in response to cultural cues” (Hong et al., 2000, p. 709). We suggest that frame switching may occur when the motivational, emotional, and cognitive processes that are adaptive to participation in the dominant culture differ from those adaptive in the heritage culture.

Third, our cultural-psychological approach suggests that immigrant minority individuals who are psychologically equipped for the central tasks in the respective cultures of engagement experience greater well-being and better health than those who are less equipped. The prediction is based on the well-established finding that monoculturals who share the dominant patterns of self and social relationships, emotions, personality, self-evaluation, and cultural meanings experience greater well-being than those who deviate from the normative patterns of the dominant culture (Becker et al., 2014; De Leersnyder, Kim, & Mesquita, 2015; De Leersnyder, Mesquita, Kim, Eom, & Choi, 2014; Dressler, 2012; Fulmer et al., 2010; Kang, Shaver, Sue, Min, & Jing, 2003; Kitayama, Karasawa, Curhan, Ryff, & Markus, 2010; Kwan, Bond, & Singelis, 1997). The prediction is also consistent with early research on sojourners establishing a beneficial effect of the fit between immigrant characteristics and the demands of the context (e.g., Kealey, 1989).

A question that remains pertains to the boundary conditions of cultural fit: What happens if members of an immigrant minority perceive that they are not welcome to participate in the dominant culture? As we see in the next sections, the benefits of psychological changes depend on the

immigration climate. That, too, follows from a cultural-psychological approach: When members of an immigrant minority are excluded from participating in the dominant culture, psychological fit will not be conducive to their well-being.

In the remainder of this chapter, we synthesize existing research on psychological acculturation. The aim is not to provide an exhaustive overview of all empirical studies—which would be a tall order given the more than 13,000 articles indexed in the 2016 edition of the Web of Science—but rather to exemplify the existing research on acculturation, and organize it from a cultural-psychological perspective. Our cultural approach will guide our synthesis of the research literature, yet it is important to note that our ability to draw conclusions is at times limited by the fact that the research itself was not informed by a cultural-psychological approach. We describe acculturation research in different psychological domains (see [Figure 19.1](#)). On the one hand, we describe changes in explicit cultural affiliation: the changes in attitudes *toward* heritage and mainstream culture, and cultural identity; on the other hand, we describe changes in other psychological domains that implicitly reflect affiliation with the culture. For each of those domains, we discuss evidence of (1) psychological changes associated with acculturation, and (2) the association of these changes with well-being and ill-being. Throughout our discussion of the literature, we highlight the role of sociocultural context to the extent possible, given the available research.

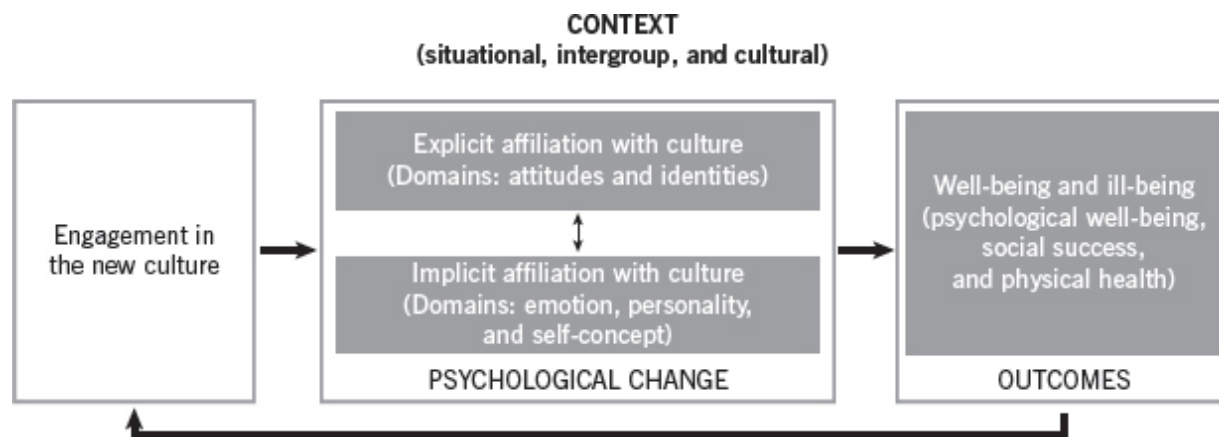

FIGURE 19.1. Model of acculturation.

EXPLICIT ACCULTURATION

A large proportion of acculturation research in psychology has focused on the important topic of immigrant minorities' relation to their heritage and the majority culture (Berry et al., 2006b; Schwartz & Unger, 2016), and the impact of acculturation on immigrant minorities' social and psychological adjustment (Schwartz & Unger, 2016). Some of this research has shown that both psychological acculturation and its outcomes are dependent on the context (i.e., the majority climate of acculturation; Bourhis et al., 1997). All these findings are discussed in more detail in this section.

Under the heading of explicit cultural affiliations, we discuss the evidence from two lines of acculturation research that in many ways converge. One line of research focuses on immigrant minority members' specific attitudes toward their (new) majority and heritage cultures. These attitudes have been referred to as acculturation "orientations," "preferences," or "strategies" (Berry, 1990, 1994, 1997, 2006), and have been measured either as attitudes proper (e.g., "I want to participate in mainstream customs and traditions") or as behaviors (e.g., "I often participate in mainstream customs and traditions"; see Celenk & Van de Vijver, 2011, for a discussion). Both measures tap into acculturation orientations, and acculturation research has made little distinction (see also Berry, 2006; Berry, Poortinga, Breugelmans, Chasiotis, & Sam, 2011).

The other line of research focuses on cultural identity, and draws on social identity theory (Tajfel & Turner, 1979, 1986). Members of immigrant minorities may have a heritage and a majority culture identity, which means that they feel like they belong to either or both of these cultural groups, and derive their positive sense of self from their membership in both groups (Deaux & Verkuyten, 2014). Cultural identity becomes salient, and may change, when immigrant minorities are exposed to cultural values and practices of the new majority culture. These changes are also considered forms of psychological acculturation. Cultural identity has been measured by questions about group membership (e.g., "In terms of ethnic group, I consider myself to be Mexican American"), group affirmation and attachment (e.g., "I am happy that I am a member of the Mexican American group"), and group exploration (e.g., "I participate in cultural practices of

Mexican American group, such as special food, music, or customs”) (Phinney, 1992; Roberts et al., 1999).

In the following sections, we describe trends in the research on explicit acculturation, which has been guided in large part by three questions. The first was whether it is *possible* to simultaneously have positive attitudes toward, or identify with, two cultures: Are cultural adoption and cultural maintenance mutually exclusive or can they coexist? The second question was how immigrants and their offspring *actually* relate to their two cultures: What are the different ways in which minority individuals relate to their culture of origin and to the majority culture? The third question is about outcomes: Which types of acculturation strategies are associated with the best outcomes? In the next sections, we describe research addressing each of these questions, with a particular focus on how context affects the answers.

Is It Possible to Affiliate with More Than One Culture?

Early acculturation research started from the assumption that immigrant minority members' endorsement of a new culture was inevitably linked to rejection of the heritage culture (Gans, 1979; Gordon, 1964; Park & Miller, 1921; Triandis, Kashima, Shimada, & Villareal, 1986), and that biculturalism was only a stop on the way to being fully acculturated (Gordon, 1964). In other words, early acculturation research assumed that acculturation was a unidimensional process. This position has received only limited empirical support. A unidimensional model better fits some findings (Flannery, Reise, & Yu, 2001; Laroche, Chankon, & Hui, 1997); it is the preferred model for first-generation immigrants (Tsai, Levenson, & Carstensen, 2000a), whose orientation to the majority culture does seem to come at the expense of maintaining the heritage culture, and for domains of acculturation that require an exclusive choice (e.g., preference for a “marriage partner”; S. Lee & Frongillo, 2003).

However, the large majority of studies have found evidence for biculturalism. Starting with studies on acculturating indigenous groups in the United States, such as Chadwick and Strauss's 1975 study (in LaFromboise et al., 1993) of Native Americans in Seattle, researchers found that immigrant minorities that endorsed the majority culture did not

abandon their heritage culture. For instance, a majority of second-, third-, and fourth-generation Chinese in the United States identified as Chinese Americans (Ting-Toomey, 1981). In some instances, later generations of immigrant minorities even revived elements of their heritage culture long after they had become full members of the majority culture. The anthropologist Roossens (1989), for example, documented how later generations of fully assimilated minority groups in Zaire, Belgium, Bolivia, and Quebec were passionate about discovering and reviving the practices of their heritage culture (see also Güngör, Phalet, & Kağıtcıbaşı, 2013; Lambert & Taylor, 1988; Maliepaard, Gijsberts, & Lubbers, 2012). Thus, immigrant minorities do not *necessarily* relinquish their heritage culture when they become identified with the majority culture, and often they identify to some degree with both.

Contemporary acculturation research has all but abandoned the unidimensional approach to acculturation, and replaced it with a bidimensional model. Biculturalism is now considered a possible end state of a process of acculturation. A large body of empirical evidence suggests that immigrant minorities are often affiliated to both the majority and the heritage culture (Berry & Sam, 1997; Phinney, 2000). One of the best known bidimensional models was introduced by Berry (1980). It maps attitudes toward the majority culture independently from attitudes toward the heritage culture. In Berry's original version, the model proposed that immigrant minorities face two fundamental questions: "Is it of value to maintain my cultural heritage?" and "Is it of value to maintain relations with the larger society?" Later authors pointed out the asymmetry of these questions (Sayegh & Lasry, 1993): Endorsement of majority culture is phrased in terms of "maintaining relations," whereas endorsement of heritage culture is not. Later scales that built on Berry's balanced the phrasing by probing for endorsement of values and engagement in practices of both the heritage and the mainstream culture (Bourhis et al., 1997), or by also probing for social contact with members of either culture (Ryder, Alden, & Paulhus, 2000).

Adopting these balanced scales, many studies have supported the idea that adopting the majority culture and maintaining the heritage culture are independent dimensions (e.g., Tsai, Ying, & Lee, 2000b; Demes & Geeraert, 2013; Ryder et al., 2000; Celenk & Van de Vijver, 2011; Zane & Mak, 2003; Y.

Zhang & Tsai, 2014). For example, Ryder and colleagues (2000) found the two dimensions to be orthogonal in five samples of East Asian Canadian students (see also Dere, Ryder, & Kirmayer, 2010; Sanchez & Fernandez, 1993; Sayegh & Lasry, 1993).

Research on ethnic identity (Phinney, 1990) similarly indicates that adoption of one cultural identity does not need to be at the expense of the other. For instance, a large-scale study on immigrant minorities in Australia yielded a positive relationship between ethnic and national identity, suggesting that those minority individuals who identified with their ethnic group tended to be the ones who felt most “Australian,” too (Nesdale & Mak, 2000).

The question of whether it is *possible* to combine two cultures has been answered affirmatively. Immigrant minorities can be, and often are, part of two cultures. The exception are domains that require an exclusive choice (e.g., marriage).

How Do Minority Individuals Actually Combine Two or More Cultures?

Different Strategies

Most of the research pertinent to the question of how immigrant minorities combine their different cultures tries to settle on a taxonomy of acculturation strategies. Researchers have proposed four acculturative “strategies” or “orientations” that combine and dichotomize the dimensions of heritage culture maintenance and majority culture adoption. Immigrant minorities are said to endorse an *integration* strategy when they are high on both maintenance and adoption. They are said to adopt an *assimilation* strategy when they are high on adoption and low on maintenance, and a *separation* strategy when they are low on adoption and high on maintenance. And finally, immigrant minorities who neither maintain nor adopt are said to choose a *marginalization* or *individualist* strategy (Bourhis et al., 1997); marginalization occurs when minority people experience anomie and therefore cultural alienation, and individualism occurs when they simply prefer to be treated–treat others as an individual person rather

than as a member of a cultural group (for a critical and thorough discussion of the marginalization concept, see Rudmin, 2006).

Despite the intuitive appeal for this fourfold typology, empirical findings to support it are rather limited. Notably, scales that are designed to measure the four strategies (e.g., Berry, Kim, Power, Young, & Bujaki, 1989; Berry et al., 2006b; U. Kim, 1984) *assume* their existence, and by themselves do not provide evidence that the model best describes the different ways immigrant minorities come to terms with their two cultures (see Chirkov, 2009, for a similar critique). Yet there is some bottom-up empirical support for the typology. In a large-scale study by Berry and colleagues (2006a) on immigrant youth in 13 countries, a cluster analysis was used to classify the roughly 5,000 participants based on not only their acculturation type but also other information. This analysis yielded four clusters of minority youth. The largest number of youth fell into what the authors called the “integrated cluster,” and these youngsters not only endorsed a preference for integration attitudes but also tended to use both the mainstream and heritage languages and had friendship networks that included youth from both the heritage and the new culture. The second- and third-largest clusters represented youth endorsing a *separationist* (or “ethnic”) and an *assimilationist* (or “national”) acculturation orientation, respectively, as evidenced by their endorsement of not only the acculturation type but also friendship patterns, cultural identification, and language use. Finally, the analysis yielded a “diffuse” cluster including youth who rejected integration but accepted the three other styles and were highly proficient in their heritage language and mainly interacted with heritage culture peers. The four empirically derived clusters therefore roughly corresponded to the four typologies; measures on identity, friends, and language corroborated the four types of acculturation styles.

A somewhat similar, yet more elaborate, typology of acculturation strategies emerged from a study in which Schwartz and Zamboanga (2008) subjected the acculturation attitudes of 436 Hispanic Americans to latent class analysis. This analysis yielded six acculturation orientations instead of the four that would be expected based on Berry’s model. In addition to an assimilationist, separationist, and undifferentiated cluster, three types of integrationist (bicultural) clusters emerged: (1) a partial bicultural cluster with moderately positive attitudes toward both cultures, (2) a full bicultural cluster with highly positive attitudes toward both cultures, and (3) a

bicultural cluster with moderately positive attitudes toward the heritage culture and highly positive attitudes toward the American majority culture. The findings suggest that Berry's conception of "integration" may encompass different acculturation strategies of combining heritage and host cultures.

The latter finding is consistent with a large literature on cultural identity, suggesting that people interacting with others from multiple cultures are likely to "have attachments with and loyalties toward different cultures" (Cheng, Lee, Benet-Martínez, & Huynh, 2014, p. 277). Many studies have yielded bicultural identity as the dominant acculturation strategy among immigrant minorities (e.g., Berry, 1974; Berry, Kalin, & Taylor, 1977; Berry et al., 2006a; Berry & Sam, 2003; Piontkowski, Florack, Hoelker, & Obdržálek, 2000; Schwartz & Zamboanga, 2008; Swyngedouw, Phalet, & Deschouwer, 1999; Vanbeselaere, Boen, & Smeesters, 2003), but biculturalism may take on very different forms. For one, the degree of identification with either culture may differ (e.g., Cheng et al., 2014). For instance, Roccas and Brewer (2002) proposed (but did not conclusively test) the existence of four strategies for dual identifiers. Individuals may identify with the intersection of multiple social groups (e.g., Asian Americans), they may identify mainly with one of two identities (either Asian or American), they may compartmentalize (Asian at home, and American at work), and they may merge the identities (identifying with both Asian and American culture simultaneously). For other typologies of multicultural identity, see LaFromboise et al. (1993; Phinney & DeVich-Navarro, 1997).

In summary, several taxonomies of immigrant minorities' acculturation strategies have been proposed, and these taxonomies have facilitated our thinking about the ways in which immigrant minorities may negotiate multiple cultures. However, empirical evidence for the most commonly used taxonomy is surprisingly scarce and suggests that the theoretical model can be refined. The ways in which immigrant minorities combine their different cultures (merge, compartmentalize, subject one to the other) should be subjects of more research.

One approach that has advanced our thinking about the ways immigrant minorities combine cultural identities was taken by Benet-Martínez and her colleagues, who introduced the concept of bicultural identity integration (BII). BII distinguishes between different types of bicultural identity. It is an individual-difference variable that measures how bicultural individuals

“perceive their mainstream and ethnic identities as compatible and integrated vs. oppositional and difficult to integrate” (Benet-Martínez & Haritatos, 2005, p. 1019; also see Benet-Martínez, Leu, Lee, & Morris, 2002; Huynh, Nguyen, & Benet-Martínez, 2011). Most research we discuss in the next section has used a single scale for BII. However, later work on BII distinguishes between two dimensions: overlap versus dissociation between the two cultures, and harmony versus tension. The relationship between these two dimensions is modest at best. Moreover, overlap and harmony have both different antecedents and different consequences (Cheng et al., 2014).

In summary, acculturation research has yielded different taxonomies or dimensions of acculturation, each describing ways in which immigrant minority individuals relate to the culture of origin and the new majority culture, respectively. Some research indicates that immigrants who both adopt the majority culture and maintain their heritage culture, combine these cultures in different ways. Insight in the taxonomy of acculturation strategies is an important first step to understanding the psychological processes underlying explicit affiliation with the two cultures, but in and of itself, it is not sufficient to understand these processes. Research that we describe in the next section, on the role of (cultural) context, reveals more about the psychological processes that constitute acculturation in explicit domains.

The Role of Context

It is increasingly clear that the context of immigration determines which strategy of acculturation (type of cultural identity) immigrant minority individuals are most likely to adopt. Society-level ideology and intergroup relations shape immigrant minorities’ acculturation strategies and cultural identification. This was recognized by Phinney and Flores (2002), who pointed out that minorities who are rejected by the majority group may increasingly identify with their heritage culture, and use it as a buffer against the negative effects of rejection (see also Crocker & Major, 1989). In his early work on acculturation, Berry also suggested the inextricability of minority acculturation orientations and majority attitudes (e.g., Berry, 1974, 1984).

Berry's view was that minorities will only choose integration when the national context endorses multiculturalism (simultaneous endorsement of both heritage culture maintenance and majority culture adoption) (Berry & Kalin, 1995; Berry et al., 1977; Kalin & Berry, 1994). Without the national endorsement of multiculturalism, and particularly when the majority discriminates and excludes the minority, minority individuals are less likely to adopt the majority culture, and are more likely to separate (i.e., to maintain the heritage culture at the exclusion of adopting the majority culture).

Social identity theory provides a theoretical framework for understanding these observations: When members of immigrant minorities perceive group boundaries to be permeable, and when becoming a full member of the majority culture is a viable option, they engage in assimilation and integration—both types of acculturation that are high on the dimension of adopting the majority culture. In contrast, when immigrant minorities experience discrimination and do not feel welcome, they are likely to segregate—a strategy that is low on the dimension of majority culture adoption (Brown & Zagefka, 2011; Schwartz et al., 2014a).

The available empirical evidence supports the idea that a welcoming national context leads to more biculturalism, and that rejection or discrimination leads to more segregation. An example is the large cross-national youth study on acculturating minority youth discussed earlier. The study yielded more biculturalism in settler countries with a long history of cultural diversity and immigration (e.g., the United States and Canada), than in nonsettler countries (e.g., the Netherlands and Germany), which are arguably less welcoming to immigrant youth (Berry et al., 2006a). In settler countries, bicultural identity at the level of the minority group was reflected by zero or positive correlations between heritage and majority culture identity; in nonsettler countries, the association at the level of the group tended to be negative, indicating that national identity came at the expense of heritage culture identity, and vice versa. Indeed, hyphenated identities are not common in Western European countries (Phalet & Kosić, 2006).

In another study, minority groups that were welcomed more by the majority in a country were more likely to endorse an integration strategy than minority groups who were discriminated. Ex-Yugoslavs in Germany and Slovakia were much more likely to endorse an integration strategy than

were Turkish minorities in Germany (46 vs. 20%; Piontkowski et al., 2000); separation was the dominant acculturation strategy among Turks in Germany (46%). The authors explain this finding by pointing to the higher levels of discrimination that Turkish immigrant minorities experience in Germany than do ex-Yugoslavs in either country (which is corroborated by other studies; e.g., Diehl, Fischer-Neumann, & Mühlau, 2016). Indeed, adoption of a separation strategy was best predicted by minorities' perceived impermeability of group boundaries (Piontkowski et al., 2000): Turkish minorities arguably coped with discrimination and exclusion by separating themselves.

Similarly, in a study with Turkish and Moroccan Muslim minorities in five different European cities, Fleischman and Phalet (2016) found that bicultural identification was more common in cities where Muslim minorities on average perceived lower discrimination based on their minority status. In these cities, minority individuals were monocultural rather than bicultural. In a different study, Verkuyten and Yildiz (2007) found that perceived discrimination negatively predicted Turkish Muslims' national (Dutch) identity, particularly for individuals who were strongly identified as Turkish and/or Muslim. For those individuals, the national identity became less viable under conditions of discrimination.

Even when immigrant minorities have dual identities, the ways in which they negotiate and combine their two cultures may be very different, in part as a function of context. Benet-Martínez and colleagues found a clear association between BII and intergroup context. On the one hand, low BII is associated with the cultural isolation and discrimination of immigrant minorities (Benet-Martínez & Haritatos, 2005). This means that in the context of (perceived) majority rejection, bicultural minority individuals experience tension and dissociation between their two cultures. On the other hand, minorities who were part of highly interconnected and mixed-ethnicity friend networks were high on BII; the association between BII and mixed-ethnic social networks held true even after researchers controlled for levels of heritage and majority culture identity (Cheng et al., 2014; Mok, Morris, Benet-Martínez, & Karakitapoğlu-Aygün, 2007). In an inclusive majority context, minority individuals thus perceived harmony and overlap between their two cultures.

Minority strategies depend on the majority context, but majority views themselves are neither stable nor homogenous; they are dependent on majority's relationship with the minority. Brown and Zagefka (2011) illustrated the dynamic relationship between minority and majority acculturation ideologies, and suggested a feedback loop: Minorities want to participate in majority culture when they perceive the majority to be welcoming and inclusive (Zagefka & Brown, 2002); in turn, majorities are more welcoming of minorities they perceive to be motivated to participate in majority culture (Zagefka, Brown, Broquard, & Martin, 2007). A vignette study illustrated the malleable nature of majority attitudes: Italian majority participants in this study were more favorable toward minorities if the latter were described as wanting contact with the majority than if they were not (Matera, Stefanile, & Brown, 2011).

Majority views are not homogenous either. Whereas the dominant majority preference in Western European contexts is for minorities to assimilate, majority individuals who have contact with minorities are less opposed to minorities' maintenance of heritage culture and, therefore, converge more with the minority preference for integration (e.g., Arends-Tóth & Van de Vijver, 2003; Van Acker & Vanbeselaere, 2011; Vanbeselaere, Boen, & Meeus, 2006; Verkuyten & Thijs, 2004). Again, there may be a negative feedback loop between majority and minority acculturation preferences, with a discrepancy in acculturation preferences that may lead to less contact and perspective taking. The latter would be responsible for a larger discrepancy between majority and minority preferences for acculturation. Over time, differences between majority individuals who do and don't have contact may be thought to increase.

Finally, not just majority attitudes are variable: There is also evidence supporting situational variations in minorities' acculturation attitudes and preferences. For instance, one study revealed that Turkish and Moroccan minority youth in the Netherlands preferred cultural maintenance at home (private domain) but adoption of the Dutch mainstream culture outside the home (public domain; Phalet et al., 2000). Similarly, first-generation Indians in the United States preferred Indian food and clothing at home but American food and clothing elsewhere (Sodowsky & Carey, 1988). Finally, Turkish Dutch minorities valued Turkish culture more positively for private domains (e.g., family and child-rearing practices) and Dutch culture more in

public domains (e.g., education; Arends-Tóth & Van de Vijver, 2003, 2004). Therefore, depending on whether attitudes or behaviors refer to the public versus the private domain, immigrant minorities may endorse more cultural adoption/maintenance, respectively.

Which Types of Acculturation Are Associated with the Best Outcomes? (It Depends on Context)

Acculturation research promises a deeper understanding of the psychological strategies that lead to immigrant minorities' psychological well-being, health, and successful adjustment to majority culture (Mui & Kang, 2006; Oh, Koeske, & Sales, 2002; Ward, 1996; Zheng & Berry, 1991). Earlier work conducted in North American contexts indicated that a bicultural or integrationist acculturation style constitutes the path to well-being and success. As we show below, research including other nations draws a picture that is slightly more complex. In this section, we make good on our promise to foreground the role of cultural context. It is our reading of the current literature that it depends on the context whether integration or biculturalism is in fact the most beneficial strategy of psychological acculturation. What follows is a synthesis of the evidence.

The consensus in acculturation research has long been that the best route to well-being and success is biculturalism or integration. For example, Berry and colleagues argued that “acculturation strategies . . . have substantial relationships with positive adaptation: integration is usually the most successful; marginalization is the least; and assimilation and separation strategies are intermediate,” and that “this pattern has been found in virtually every study, and is present for all types of acculturating groups” (Berry, Poortinga, Segall, & Dasen, 2002, p. 368; see also Berry, 1997; Berry, Kim, Minde, & Mok, 1987; Berry & Sam, 1997; Zheng & Berry, 1991).

Similarly, in one of the first review articles dedicated to biculturalism, LaFromboise and colleagues (1993) pointed to the risks for individuals who shed their culture of origin in favor of a new culture, and proposed instead that acquiring the majority culture, while also maintaining the culture of origin, produces the best outcomes for immigrant minorities. They cited research showing the psychological ill-being of Native American individuals

who assimilated to the majority culture but encountered an impermeable barrier to their participation in it (Kerckhoff & McCormick, 1955, as cited in LaFromboise et al., 1993). According to LaFromboise et al., biculturalism leads to better physical and psychological health for minority individuals, in part because it buffers against rejection by members of either culture. In the work of LaFromboise et al., “biculturalism” refers to a large variety of domains, including identification with and positive attitudes toward both cultures. It is crucial to keep in mind that this consensus was based on research conducted in the United States and Canada—contexts that are known for their multicultural policies. Research sampling from a broader range of cultures suggests that the adaptive value of integration and biculturalism is dependent on the context. A chapter drawing on the large-scale cross-cultural youth study on acculturation found that “separation” was no worse than “integration”; both strategies were positively related to psychological well-being (i.e., good mental health) and sociocultural well-being (i.e., social competence in managing daily life; Vedder, Van de Vijver, & Liebkind, 2006). Assimilation did seem less beneficial to psychological well-being than either integration or segregation, as it was only modestly related to sociocultural well-being, and not at all to psychological well-being. The research also suggested that perceived discrimination renders integration strategies less likely. Therefore, members of immigrant minorities who experienced discrimination were more likely to resort to segregation, which offered them an alternative route to well-being from integration.

A meta-analysis on biculturalism by Nguyen and Benet-Martínez (2013) is inconclusive as well, as we discuss below. The objective of the meta-analysis was precisely to test whether biculturalism is more beneficial to immigrant minorities than exclusive identification either with the dominant or the heritage culture. A literature search obtained 83 studies in which biculturalism was measured and related to at least one domain of well-being. These studies measured biculturalism in terms of acculturation attitudes, behaviors, identities, and values. The meta-analysis yielded support for the benefits of biculturalism, when aggregating across different cultural (national) contexts. The authors compared the beneficial effects of biculturalism and either heritage or dominant culture identification for studies that use bidimensional measures, and found a larger association

between well-being and biculturalism/integration (unweighted mean effect size $r = .70$) than between well-being and either the dominant (effect size $r = .62$) or the heritage culture orientation (effect size $r = .56$). However, these associations were all aggregated *across national contexts*.

There is reason to doubt that biculturalism was the most beneficial strategy in each national context. First, there was substantial variation in effect sizes across different studies (r s ranging from $-.78$ to $+.87$). Second, biculturalism was a much stronger predictor of well-being in the two-thirds of the studies conducted in the United States ($r = .62$) than the one-third conducted in other, non-U.S. cultural contexts ($r = .32$). Importantly, the meta-analysis never compares the impact of biculturalism as opposed to segregation or assimilation in the non-U.S. cultural contexts (as the authors acknowledge: Nguyen & Benet-Martínez, 2013, p. 127). Therefore, the meta-analysis does not answer the question of whether biculturalism is the most beneficial strategy in non-U.S. immigration contexts as well.

Research from Western European contexts suggest that biculturalism is not invariantly beneficial, but that its adaptive value depends on context. One study with Turkish Belgian young adults found biculturalism to be either the best or the worst strategy for school success, depending on the level of discrimination experienced (Baysu, Phaet, & Brown, 2011). Biculturalism was associated with the best school careers (as retrospectively reported) when minorities had experienced low levels of discrimination. However, biculturalism predicted the worst school careers for members of minorities who had experienced high levels of discrimination. In contrast, separated and assimilated minorities did no worse in school when they experienced discrimination than when they had not. Biculturalism, and not the other two strategies, made immigrant minorities vulnerable. It therefore appears that biculturalism is a successful strategy in nations/contextes that allow for coexistence of ethnic and national identities, but not in contexts that offer less opportunity to be part of both cultures. As Schwartz and colleagues phrase it: “On the surface, biculturalism may seem to be an obviously preferable strategy, offering ‘the best of both worlds’ to the acculturating migrant . . . but migrants may often find themselves ‘caught between two worlds’ ” (Schwartz, Vignoles, Brown, & Zagefka, 2014b, p. 77; see also Rudmin, 2003). When immigrant minorities are caught between two worlds, biculturalism appears to be less beneficial.

In summary, we suggest acculturation strategies and cultural identification derive meaning from the specific immigration context. This is consistent with a cultural-psychological perspective in which the meaning of behavior necessarily derives from the cultural context in which it occurs. Integration or biculturalism by themselves are not beneficial, but they may be healthy ways to achieve psychological acculturation when the dominant culture is inclusive of minorities. It is conceivable that the role of immigration context may have become invisible to researchers, because many of the early acculturation studies were conducted in countries with a tradition of immigration and an ideology of multiculturalism (Canada, United States). Based on recent findings from other immigration contexts, we suggest that the level of discrimination and inclusiveness determines whether segregation becomes a more beneficial strategy than integration. Future research on the role of acculturation strategy in well-being should take the (national) immigration context into consideration.

We are certainly not the first to take context into consideration. It is the key tenet of the interactive acculturation model (IAM) developed by Bourhis and colleagues (1997) that the fit between the acculturation attitudes of minority and majority groups, rather than the acculturation strategy itself, predicts minority well-being—both psychological and social well-being. In a nationally representative study of Belgian middle schools, Celeste, Meeussen, Verschueren, and Phalet (2016) put the IAM to the test by investigating how the fit between minority acculturation strategies and the acculturation preferences of their majority peers predicted the social well-being of minority students. Controlling for minorities' own acculturation preferences, the fit between acculturation norms in Turkish and Moroccan minority youth and their Belgian classmates predicted peer rejection. Minority students' biculturalism was only associated with less peer rejection when the majority classmates also favored biculturalism. Notably, when the majority endorsed a norm for assimilation, minorities with a preference for integration (biculturalism) were more likely to be rejected by their peers than other minority kids, even the ones who preferred segregation. It is important to note that this type of misfit between the majority preference for assimilation and the minority preference for integration (biculturalism) is found to be very prevalent in Western European contexts (discussed previously; Vanbeselaere et al., 2006); research

by Celeste and her colleagues (2016) found that it comes at a high cost for minority individuals, at least in terms of peer rejection.

Minority group members' *perception* of majority group members' expectations, and majority *perception* of minority acculturation attitudes, may be as powerful in predicting well-being as the actual attitudes held on both sides (see the concordance model of acculturation [CMA]; Piontkowski, Rohmann, & Florack, 2002). For instance, when immigrant minority members perceive that the majority wants them to assimilate more than is comfortable for them, this may result in lower well-being, especially among respondents high on conformity (Roccas, Horenczyk, & Schwartz, 2000). Perceived conflict between ingroup and outgroup acculturation expectations also impacts psychological and social well-being. For example, Israeli immigrant adolescents from the former Soviet Union felt caught between what they perceived to be the expectations of their two reference groups, and this affected their well-being. Those who perceived that their Israeli peers expected more assimilation and less segregation than was comfortable for them had low sociocultural well-being (primarily school adjustment); those who perceived that their co-ethnics expected less assimilation and more segregation than was comfortable for them had low psychological well-being (Horenczyk & Sankevich, 2006).

Summary: Explicit Acculturation

Immigrant minorities position themselves with regard to both their heritage and their dominant culture. We have called this positioning "explicit acculturation," because it involves an explicit affiliation with either culture or both. We reviewed the extant literature to answer three questions:

1. Is it possible to affiliate with more than one culture? The answer is clearly affirmative. Biculturalism is possible and widespread.
2. In what different ways do minority individuals actually combine two or more cultures? To our surprise, we found a dearth of descriptive evidence on the *actual* strategies that immigrant minority members adopt to combine their different cultures. There is some evidence to support Berry's influential framework of acculturation that proposes independent dimensions of

adoption of the majority culture and maintenance of the heritage culture. However, it also seems clear that there may be many different ways for minority members to integrate their different cultures, and with exception of research on BII, little is known about the ways minorities integrate their different cultures. We also examined the conditions under which certain strategies of acculturation prevailed and found that immigrant minorities negotiate their cultural affiliation within the space created by majority–minority relations (Wakefield et al., 2011). When the majority is accepting of diversity, or when intergroup relations are harmonious and inclusive, the most common type of affiliation for minorities is integration or biculturalism. When the majority context is less welcoming, and when there is discrimination, immigrant minorities *as a group* are more likely to choose ethnic identity/segregation.

3. Which types of acculturation are associated with the best outcomes? Our answer is that it depends on the context. Integration and bicultural identity are conducive to positive outcomes when the majority context is inclusive, but in the absence of majority acceptance and support, segregation and ethnic identity may serve minority individuals better.

IMPLICIT CULTURAL AFFILIATION

With some notable exceptions that we describe below, acculturation research has focused on immigrant minorities' explicit affiliation with majority and ethnic culture. From a cultural-psychological point of view, minorities that engage in a majority culture face many more tasks than to position themselves explicitly with regard to their cultural groups. They interact with majority others and during these interactions develop (new) self- and other-understandings. They negotiate the practices and institutions of the majority culture, and in so doing, use the majority language, as well as engage in the system of meanings and meaning making of the new culture. On an everyday basis, immigrant minorities therefore judge, feel, and act in the situations they encounter in the majority culture. These “basic” psychological processes—cognition, emotion, acting, self-understanding, meaning making (e.g., values)—acculturate them (i.e., change because members of minorities engage in the minority culture). We propose that

these changes occur because of affordances, constraints, and reward structures available in the majority culture, and do not require that immigrant minorities identify with or *want* to be part of the majority culture. Shifts in basic psychological processes toward the majority norm reflect acculturation but are implicit ways of affiliating.

Acculturation therefore involves all processes that are subject to systematic and meaningful cultural differences (e.g., self-understanding, emotion, values, cognition), and that help a minority individual to successfully perform the “cultural tasks” of the new or majority culture (Kitayama et al., 2009; Markus & Hamedani, 2007; Shweder, 1995). These psychological processes may be thought to constitute “cultural competence,” as it was described in an early review (LaFromboise et al., 1993). The authors of that review proposed that biculturals need to develop cultural competence in two cultures, and defined cultural competence as a “multilevel continuum of social skills and personality development,” including to “(a) possess a strong personal identity, (b) have knowledge of and facility with the values of the culture, (c) display sensitivity to the affective processes of the culture, (d) communicate clearly in the language of the given cultural group, (e) perform socially sanctioned behavior, (f) maintain active social relations with a group, and (g) negotiate the institutional structures of that culture” (p. 396). They noted that “the length of this list reflects the difficulty involved in developing cultural competence, particularly if one is not raised within a given culture” (p. 396), and “assume that the more levels in which one is competent, the fewer problems an individual will have functioning effectively within two cultures” (p. 396).

If we accept the basic premise of cultural psychology—that psyche and culture are mutually constitutive—and apply it to acculturating individuals, then immigrant minorities that participate in two (or more) cultures become bicultural with respect to all psychological processes implicated in their contexts of participation. These processes include, or may even go beyond, the different aspects of competence listed by LaFromboise and colleagues (1993). In the next sections, we discuss two domains of implicit cultural affiliation: emotion and personality. These two domains are representative, but not exhaustive of research on implicit acculturation (see also Heine & Lehman, 2004; Güngör, De Leersnyder, Coşkan, Phalet, & Mesquita, 2018; R. Zhang & Li, 2014).

Emotion

Emotional acculturation is an important aspect of becoming part of a culture. In order to fit in and get along, individuals need to have the right emotions. Emotional acculturation is not only a necessary but also a deep way of becoming part of a new culture; it involves being able to make meaning of new situations according to majority goals and values, and thus to share a social reality with majority others.

Emotions differ systematically across cultures in ways that tie individuals to the values and goals that are central in their cultures (e.g., Boiger, Güngör, Karasawa, & Mesquita, 2014b; Boiger, Mesquita, Uchida, & Barrett, 2013; Kitayama, Mesquita, & Karasawa, 2006; Mesquita, 2003; Mesquita, De Leersnyder, & Boiger, 2016; Mesquita & Leu, 2007; Tamir, Bigman, Rhodes, Salerno, & Schreier, 2015; Tsai, Knutson, & Fung, 2006). In a culture that values autonomy, individuals are more readily angry (United States, Western Europe) than in a culture that values interpersonal harmony (East Asian cultures) (Mesquita, Marinetti, & Delvaux, 2012; Solomon, 1978). One way to understand these cultural differences is that individuals appraise events and situations from the perspective of the cultural values (De Leersnyder, 2014; De Leersnyder, Koval, Kuppens, & Mesquita, 2017; Mesquita, De Leersnyder, & Albert, 2014). Therefore, if a person moved from a culture that gives primacy to achievement and self-direction to a culture that prioritizes interpersonal harmony, he or she should come to experience less anger over time. This is an example of “emotional acculturation.”

The first evidence for emotional acculturation came from a study comparing emotional experiences in immigrant minority groups in two national contexts, the United States and Belgium (De Leersnyder et al., 2011); participants were adult Korean Americans in the United States and Turkish minorities in Belgium. These specific immigrant groups were chosen because the emotional patterns that are typical for their heritage culture are known to differ from those that are typical for their majority culture (De Leersnyder et al., 2015; Kitayama et al., 2006; Mesquita, 2001); therefore, acculturation of emotions should involve measurable shifts.

Emotional acculturation was measured by calculating the fit of minority participants’ emotional experiences to the average emotional experience of majority members in similar situations. In the study, we asked both majority

and minority participants to describe a recent emotional situation from their own daily life that matched a given prompt. Prompts were chosen to be cross-culturally relevant and to cover a large range of emotional situations. The eight prompts that were used in the study varied according to valence (positive or negative), autonomy versus relatedness promotion, and context (work/school or home). An example of a prompt for a negative relatedness-promoting emotional situation in a work or school context would be: “Please think about a recent occasion at school or at your work in which you felt bad about your relationships with others (e.g., feeling ashamed, guilty, indebted).” After participants described the situation they had encountered, they rated their experience of that situation with respect to 20–30 emotions that covered the full range of the emotional domain. When we calculated emotional fit, we included those emotions that were equivalent in meaning across different groups. This method yielded emotional profiles for each participant in each type of situation. We calculated emotional fit by means of profile correlations ([Figure 19.2](#)).

FIGURE 19.2. Example of an emotion pattern: Belgian respondent in a negative disengaged situation. From De Leersnyder, Mesquita, and Kim (2011).

We compared the (Fischer transformed) profile correlations of Korean and European Americans, respectively, with the average European American emotion pattern in similar situations; and similarly, we compared the profile correlations of Turkish Belgian and Belgian participants, respectively, with the average Belgian emotion pattern in similar situations (see Figure 19.3). The emotional fit of immigrant minority groups was consistently lower than that of majority individuals²; yet, indicative of emotional acculturation, the fit of second-generation immigrants was higher than that of first generation (De Leersnyder et al., 2011). Lower fit in the first-generation immigrant

minorities was *not* caused by random answers: The variance did not differ between first-generation immigrant minorities and the majority group.

FIGURE 19.3. Group differences in emotional fit to the average majority member. * $p < .05$; † $p \leq .10$.

Furthermore, emotional fit was associated with the time spent in the new culture and the age of immigration, which is another indication that emotions acculturate (De Leersnyder et al., 2011). Moreover, immigrant minorities' number of social contacts with majority members, which can be considered a measure of immersion in the culture, was predictive of their emotional fit with the mainstream culture—for Korean minorities, social contact predicted emotional fit in both positive and negative situations; for Turkish minorities, it predicted emotional fit in negative situations only. The negative intergroup climate for Turks in Western European countries, as compared to the U.S. climate for Koreans at the time of the study may explain these differences, although the underlying process is yet unclear.

Further evidence for emotional acculturation comes from a large representative study in Belgian middle schools, in which we oversampled the minorities (the same study as reported by Celeste et al., 2016). This study included minorities ($N > 1,100$) from around 100 different countries of origin, but about 26% of them were of Turkish and Moroccan descent, two of the largest minority groups in Belgium. We used a similar method to the one described for the adult study, and found that minorities' emotional fit with the majority average was higher in each subsequent generation until, in the third generation, it was no longer distinguished from the fit of majority youth; again, these findings are suggestive of emotional acculturation (Jasini, De Leersnyder, Phalet, & Mesquita, 2018b) (Figure 19.3). When we calculated emotional fit, based on the average emotions of majority students in the *classroom*, the patterns of fit across generations of immigrants were similar to those obtained with the average emotions of all majority students in the sample.

Emotional Acculturation in Context

Research on emotional acculturation suggests an important role for context. When minority individuals engage in social relations with others in the culture, their emotions acculturate. As part of our representative study in Belgian middle schools, we found that minority students nominated as friends by their majority peers were more emotionally acculturated. One interpretation of this finding is that minorities' emotions are "socialized" during interactions with majority classmates, in much the same way infants learn during their interactions with caregivers (Saarni, 2008). This means that contexts that allow immigrant minorities to have interactions with majority others promote emotional acculturation.

We also found that minority adolescents who reported speaking their heritage language (e.g., Turkish, Moroccan) at school were less emotionally acculturated, as measured by their emotional fit with the average Belgian student in our sample (Jasini et al., 2018b). If heritage and majority language are a zero-sum game, these were the minority students who did not engage with Belgian majority students as much, possibly because of discrimination and rejection.

Data from the first two waves of the longitudinal part of the nationally representative school study in Belgium suggested that an unwelcoming context, as measured by peer rejection and teacher discrimination, longitudinally predicted lower emotional fit 1 year later (Jasini, De Leersnyder, Phalet, & Mesquita, 2018a). This finding speaks to the importance of acculturation context to an implicit domain of psychological change, such as emotions. Kids who encountered discrimination were less likely to have emotions similar to their majority peers 1 year later than did kids who had met with more welcoming environments.

Not only fit with majority culture emotions but also fit with the heritage culture emotions seems to be achieved during interaction with others from the culture. There is some initial evidence that social engagement in heritage culture contexts also predicts fit with the heritage culture emotions. When we looked at the emotional fit of the Korean American adults with Koreans in Korea, and of Turkish Belgian adults with Turks in Turkey (De Leersnyder et al., 2011), we found that those with heritage culture friends had higher fit (De Leersnyder et al., 2015). Yet, again, immigrants who socially engaged in the pertinent cultural context had the emotions of the heritage culture.

Finally, several studies suggest that emotional experiences tend to fit the demands of the cultural context, either heritage or majority. In a daily diary study (Perunovic, Heller, & Rafaeli, 2007), Asian Canadians reported more Asian emotions when interacting with other Asian Canadians than when they interacted with European Canadians. The authors measured “Asian emotions” in terms of dialecticism: the co-occurrence or compatibility of positive and negative emotions. They found that Asian Canadians reported higher compatibility of positive and negative emotions in the context of interactions with co-ethnics than in the context of interactions with majority (European Canadian) others.

In one of our own studies with Korean Americans and Turkish Belgians, we found that minority emotions fit the majority emotions at work, and the heritage emotions at home (De Leersnyder et al., 2015); when aggregating across different contexts, the levels of minorities’ fit to heritage and majority culture were of comparable size.³ The finding suggests that minority individuals “regulate” their emotions to fit the demands of the cultural context. It also suggests that learning to have the emotions of the new

culture does not necessarily mean losing one's ability to feel in ways that fit the heritage culture.

In an experiment from our own lab, we manipulated the cultural context and observed differences in emotions *expressed*. The design was based on the paradigm of cultural frame switching (e.g., Hong et al., 2000). In the current experiment, Turkish Belgian biculturals were assigned either to a Belgian or to a Turkish setting (De Leersnyder & Mesquita, 2014). Culture was cued by the study location (Belgian community center vs. social room in the mosque), the ethnicity of the experimenter and the confederate (Belgian, Turkish), and the language spoken during the experiment (Dutch, Turkish). In the Belgian context, we expected autonomy to be salient, and in the Turkish context, community (Shweder, Much, Mahapatra, & Park, 1997). Consistent with previous research (Rozin, Lowery, & Haidt, 1999), we also expected that autonomy violations would elicit more anger, and violations of community, values more contempt. In our experiment, the confederate misbehaved several times in ways that were scripted and standardized across experimental conditions.

Some of these misbehaviors were violations of autonomy (as pilot-tested in both Belgian and Turkish contexts), and they were followed by more observed anger rather than contempt in both conditions. Other misbehaviors were clear-cut violations of community, and they were associated with contempt rather than anger, also across the Belgian and Turkish conditions. When misbehaviors were ambiguous violations that could be interpreted to pertain to either autonomy or community, we expected biculturals to interpret those violations according to the salient values in the cultural condition, and thus show anger in the Belgian and contempt in the Turkish condition. Most importantly, we expected that biculturals would express different emotions, depending on the cultural condition to which they were assigned. As expected, we found relatively more anger than contempt in the Belgian condition, where we expected biculturals to interpret the ambiguous misbehaviors as violations of autonomy. In the Turkish condition, we expected community values to be salient, and therefore, more contempt than anger. The findings confirmed the expectation that cultural contexts, given differences in salient values, give rise to different observed emotions. In the Turkish condition, biculturals expressed much less anger than they did in the Belgian

condition. However, we did not find more contempt than anger, as we had expected; for a reason to be further explored, we found that the levels of expressed anger and contempt were similar in the Turkish condition.

Emotional Acculturation and Well-Being

Evidence that emotional acculturation is conducive to well-being is limited. The strong association between social contact and emotions suggests that emotional acculturation promotes sociocultural well-being, but cross-sectional research does not adequately distinguish between cause and effect. Our longitudinal study with minority students in Belgian middle schools points to the positive influence that minorities' emotional acculturation has on their contact with majority peers. Emotional fit in the first year predicted self-reported number of Belgian friends the next year.

A large-scale study among immigrant minority women from Haiti, the Dominican Republic, the English-speaking Caribbean, and Eastern Europe, found an association between the lack of emotional fit with U.S. emotions and somatic complaints, another aspect of well-being (Consedine, Chentsova-Dutton, & Krivoshekova, 2014). In this study, emotions were measured as trait anger and trait anxiety.

Although we know of no other evidence for the link between emotional acculturation and well-being, indirect support for the significance of emotional fit comes from findings with monoculturals. In one study, we found that European American, Korean, and Belgian monoculturals whose emotions during relational situations were more like those of others in their culture reported higher relational well-being (De Leersnyder et al., 2014). In other research, we have found that individuals reported higher *psychological well-being* (i.e., feeling good about oneself, having no symptoms of depression) when their emotions were more similar to those of others in their culture. However, the link between emotional fit and psychological well-being was significant only for emotional fit in situations that were particularly instrumental to the central cultural goals. Fit in autonomy-promoting situations at work for European Americans, relatedness-promoting situations at home for Koreans, and both autonomy- and relatedness-promoting situations for Belgians were associated with higher

psychological well-being (De Leersnyder et al., 2015). Together, these findings suggest that emotional fit with one's culture is beneficial in certain situations. It is not clear under what circumstances the same would be true for biculturals; future research should address this question.

Summary: Emotion

Emotions form one domain of implicit acculturation. As individuals engage in a new culture, they start experiencing emotions that are more similar to those of the majority culture, that is, emotions that reference the new culture's values. Acculturation toward the new culture's emotions does not mean the exclusion of heritage culture emotions. Rather, engaging in the heritage culture (e.g., by having heritage culture friends) independently predicts fit with the average heritage emotions. We also have some indication that the culture of the specific interaction context primes emotional patterns that fit the pertinent culture.

Personality

Personality traits describe systematic individual differences in behavior (Buss & Craik, 1983; Church, Katigbak, Miramontes, & Del Prado, 2007). Extraverts tend to be assertive, outgoing, and energetic, and introverts are less assertive, keep to themselves more, and like quiet or calm. Personality traits correspond to stable behavioral tendencies, either across (Kwan et al., 1997) or within situations (Fleeson, 2001). An example of the latter would be an individual who is an extravert at home, and an introvert in big groups. Acculturation of personality, thus conceived, implies a shift in the behavioral tendencies of immigrant minority individuals because of their exposure to the majority culture.

Culture importantly accounts for variability in personality (e.g., Allik & McCrae, 2004; Güngör et al., 2013a; McCrae et al., 2010; Schmitt, Allik, McCrae, & Benet-Martínez, 2007; Chopik & Kitayama, 2017). For instance, North Americans are more extraverted and open, and less neurotic and agreeable than East Asians (e.g., Allik & McCrae, 2004; Güngör et al., 2013a; McCrae, Yik, Trapnell, Bond, & Paulhus, 1998). This means that individuals

may undergo changes in personality profile, simply because they are exposed to other cultural influences. For instance, moving to North America may afford extraversion (sample items: energetic, enthusiastic), because everyday life consists of high-activation activities (e.g., Tsai, Miao, & Seppala, 2007). Similarly, moving to Japan may afford neuroticism (sample items: tense, irritable, moody) because of the relative acceptance of negative emotions in East Asian cultural contexts (e.g., Miyamoto, Ma, & Petermann, 2014). Several studies suggest the acculturation of personality (see Gillin & Raimy, 1940, for the earliest one).

On the one hand, some studies have yielded personality profiles of immigrant minorities that averaged between those of the new majority and those of the heritage culture. For instance, aggregating across different generations, McCrae and colleagues (1998) found that Chinese Canadians' scores on the Big Five averaged between those of Chinese people from Hong Kong and European Canadians. In one of our own studies (Güngör et al., 2013a), we compared the personality profiles reported by first-generation Japanese American mothers with those of their native counterparts in Japan, as well as North America. Calculating each participant's fit with the average Japanese and the average European American personality profile, respectively, we found that the personality profile of these Japanese American mothers was dissimilar from the Japanese average personality, but had not shifted toward the European American profile (there were no differences in fit between the Japanese American mothers and their Japanese counterpart with respect to fit to the European American personality pattern). The absence of Japanese cultural affordances therefore seems to have been more powerful in constituting personality changes than the presence of American cultural affordances.

Without any information about the process of acculturation, these studies should be interpreted with caution. It is possible that the different personality profiles of immigrant minority and heritage culture samples may be due to self-selection as much as to the process of acculturation. In McCrae et al.'s (1998) study, Chinese immigrants to the United States may be self-selected to be more American than their compatriots who stayed in China; similarly, in our own study with Japanese American mothers, it is possible that Japanese mothers who moved to the United States were, to

begin with, less similar to the Japanese averages of Extraversion and Conscientiousness than their counterparts who stayed in Japan.

Research showing that immigrant minorities resemble the majority culture's personality profile more with each subsequent generation is more convincing in this regard. Self-selection does not explain the generational pattern of increased fit. In a study by Benet-Martínez and Karakitapoglu-Aygun (2003), first-generation Asian Americans were found to be less extraverted and open, and more conscientious than later generations of Asian Americans. The research did not distinguish between shedding heritage culture personality and acquiring majority culture personality. It is conceivable that increased engagement of second and later generations of immigrants in majority culture contributes to a more acculturated personality than that of first-generation immigrants.

Personality, or the stable behavioral tendencies that it represents, may also differ by context (Fleeson, 2001). For biculturals, personality profiles may differ per relevant cultural context. Several studies are suggestive of this idea. In one study, bilingual Mexican Americans who completed the Big Five Questionnaire were more extraverted, agreeable, and conscientious in English than in Spanish—and these differences were analogous to the differences between North American and Mexican personality profiles (Ramírez-Esparza, Gosling, Benet-Martínez, Potter, & Pennebaker, 2004). Interestingly, biculturals' personality profiles correlated highly in English and Spanish (mean $r = .80$), which suggests that “individuals tend to retain their rank ordering within a group but the group as a whole shifts” (Ramírez-Esparza et al., 2004, p. 115).

That these findings are not necessarily due to language use only is suggested by an observational study with Hong Kong Chinese–English bilinguals. Bilinguals were observed by others as they conversed with either European American or Chinese interviewers. Observers perceived the bilinguals to be more extraverted, open, and assertive when they talked with European American than with co-ethnic Chinese interviewers, regardless of the language of the interview (English, Chinese). The researchers' interpretation is that the “presence of a native English speaker is strong enough to prime these Western traits and elicit accommodating patterns, regardless of the language used” (Chen & Bond, 2010, p. 1525)—a phenomenon that has also been referred to as the “interlocutor effect.”

But is personality acculturation beneficial? Evidence is both scarce and mixed. Some studies have found that personality fit with the majority culture, not the personality profile itself, is associated with immigrant minorities' well-being (e.g., lower levels of depression) (e.g., Ward & Chang, 1997); yet other studies have found the personality profile itself is predictive of well-being and that fit with the majority culture is not (fit here is measured as discrepancy scores; Ward, Leong, & Low, 2004). More research on this topic is needed. We predict that personality fit is more important to immigrant minorities' well-being insofar as the associated behavioral tendencies are culturally defining. For example, it may be more important to fit with regard to Openness (e.g., imaginative, artistic, unconventional) than with regard to Agreeableness in the United States, because of the high value attached to uniqueness (Kim & Markus, 1999). We also predict that personality fit with the majority culture is particularly important in domains where immigrant minorities engage with the majority culture; for instance, it would be more important that immigrant minorities in the United States be open in academic environments than at home. Research on the effects of personality acculturation on well-being would benefit from such theorizing.

Summary: Personality

Personality may be another domain of implicit acculturation. Because cultures systematically differ in the kinds of behavior they afford, we expect that exposure to a new culture may lead to changes in personality (i.e., the disposition to certain kinds of behavior). Taken together, different types of research suggest that acculturation of personality may indeed occur. On the one hand, several studies have shown that immigrant minorities' personality profiles fall in between those of their heritage and majority culture counterparts. On the one hand, there are studies showing generational increments of personality fit with the majority culture. Less is known about the conditions under which personality acculturation occurs in immigrant minorities, and positively contributes to minority adjustment.

Summary: Implicit Cultural Affiliation

There is acculturation of “deep” psychological processes, such as emotions and personality. When immigrant minorities engage in majority cultural contexts, they may come to feel and behave in ways that suit the majority culture; that is, their emotions and personality (behavioral tendencies) may change to fit the demands of the cultural tasks. Due to a scarcity of research, there is yet very little evidence that cultural fit of those deep psychological processes contributes to well-being. The role of context is similarly understudied. However, so far we have found evidence that an unwelcoming environment interferes with acculturation of implicit domains: Discrimination longitudinally predicted less emotional fit with the majority culture 1 year later. We predict that acculturation occurs primarily with respect to the psychological domains that are culturally central (e.g., anger in a culture of autonomy; openness in a culture that values uniqueness); the jury is still out on this prediction. Similarly, we expect that those psychological changes that are central to the individual’s functioning in the majority culture impact well-being most. A lot of research remains to be done in this area. Finally, we have found for both emotions and personality that the relevant cultural context determines which emotions and personality traits are activated. Therefore, it may be more productive to look at the acculturation of implicit domains as a situated process rather than merely as an individual-difference variable.

HOW DO CHANGES IN EXPLICIT AND IMPLICIT CULTURAL AFFILIATION RELATE?

We have distinguished between explicit domains of acculturation, in which an individual explicitly determines his or her position with regard to each culture of engagement, and implicit domains of acculturation, which concern an individual’s fit with majority psychological processes. An important question is how the two relate. Do minority individuals who identify with the majority culture, or who want to be part of it, think, feel, and act more like majority individuals than do minority members who distance themselves from the majority culture and segregate? And how does biculturalism in explicit domains of acculturation (e.g., simultaneously identifying with both the heritage and the majority culture) affect

biculturalism in implicit domains (e.g., emotional frame switching)? By trying to answer these questions, we will be able to draw a more complete picture of the acculturation process.

The relationship between explicit and implicit domains of acculturation is not straightforward. Some research indicates that explicit acculturation does indeed predict acculturation in implicit domains. Japanese exchange students in Canada who endorsed the Canadian lifestyle (i.e., who endorsed either assimilation or integration on Berry's questionnaire of acculturation types; Berry et al., 1989; in Heine & Lehman, 2004), reported higher levels of self-esteem than those who did not (Heine & Lehman, 2004, Study 2c). Because self-esteem has been found to be higher in North American than in Japanese contexts (Heine, Lehman, Markus, & Kitayama, 1999), the finding is indicative of the relationship between explicit and implicit acculturation. Similarly, Chinese Canadians' willingness to adopt Canadian culture predicted independence in self-construal, whereas their preference for maintenance of the Chinese culture predicted their interdependence (self-construal measured by Singelis's independence and interdependence scale; Singelis, 1994; Ryder et al., 2000). Again, independent self-construals are more prevalent in the North American context, and interdependent self-construals in East Asian contexts (Markus & Kitayama, 1991a); the finding suggests that explicit and implicit acculturation go hand in hand.

In other research, Asian Americans' acculturation attitudes toward the dominant U.S. culture (measured by the Stephenson Multigroup Acculturation Scale–Dominant Society Immersion [SMAS-DSI]; Eap et al., 2008) were positively associated with Extraversion and Conscientiousness, personality traits that have been found to be more common in European American than in Asian American individuals, but they were negatively related to Neuroticism, a personality trait that was more prevalent in Asian American than in European American contexts. In our own study on personality acculturation with Japanese American mothers, we found that immigrant mothers whose attitudes toward European American culture were more favorable (as measured by the Japanese American Acculturation Scale; Suinn, Rickard-Figueroa, Lew, & Vigil, 1987) better fit the American levels of Openness, Neuroticism, and Conscientiousness, the personality traits that differed most between European American and Japanese contexts (Güngör, Fleischmann, Phalet, & Maliepaard, 2013b).

In contrast, in emotional acculturation research with adult samples of Korean Americans and Turkish Belgians, we failed to find an association between explicit and implicit acculturation, with one exception that we discuss below (De Leersnyder et al., 2015). We used the Vancouver Index of Acculturation (VIA; Ryder et al., 2000) to measure explicit acculturation (i.e., acculturation strategies). Our studies yielded two different subscales of the VIA (for majority culture): one describing the adoption of majority values, customs and traditions; the other, the desire for contact with majority others. We failed to find a relationship between acculturation of values, customs, and traditions, and emotional acculturation: Wanting to be part of majority culture was not predictive of feeling the right emotions. In Belgium, we also failed to find a link between wanting contact with majority others and emotional acculturation. However in the U.S. context, wanting contact with majority others was related to emotional acculturation. In the U.S. context, explicit acculturation predicted implicit acculturation. The reason that desire for contact predicted emotional acculturation in Korean Americans, but not in Turkish Belgians, may be that it was differentially related to actual contact in those two immigration contexts: Korean Americans who wanted contact with the majority reported having majority contacts, but Turkish Belgians wanting contact with majority Belgians were often unable to realize this desire (i.e., zero correlation between desired and actual contact with majority). Therefore, the relationship between explicit and implicit acculturation may have depended on the possibility to realize explicit acculturation preferences. Immigrant minority members' desire to be part of majority culture may only predict implicit domains of acculturation to the extent the majority culture is welcoming and inclusive. As we have seen before, this is not always the case. In fact, research in Western European contexts suggests that immigrant minorities tend not to be accepted unless and until they become completely indistinguishable from the majority (Van Acker & Vanbeselaere, 2011), a feat that is hard to accomplish (and conceivably undesirable) for many.

Research on individual differences in BII also teaches us about the relationship between explicit and implicit acculturation, and the importance of context for this relationship (e.g., Cheng et al., 2014). In frame-switching studies, individuals identifying with two cultures do not always show preferences or behavior that fits the cued cultural context. Several studies

have suggested that whether biculturals show psychological tendencies that are consistent with the context they are in (i.e., whether they show implicit acculturation) depends on their BII. Compared to individuals high on BII, individuals low on BII show less implicit acculturation. Studies focusing on implicit acculturation have made use of a cultural frame-switching paradigm (Hong et al., 2000). Whereas individuals high on BII showed responses that were consistent with the majority culture when the majority culture was primed, individuals low on BII showed more heritage culture responses when the majority culture was primed (Mok & Morris, 2013). Thus, high-BII individuals showed assimilative, and low-BII individuals showed contrastive cultural frame switching.

Mok and Morris (2013) explain contrastive cultural frame switching from biculturals' self-protective motives: Low-BII individuals, cued with one cultural identity, perceive threat to the other. Contrastive frame switching is seen as an attempt to reaffirm the threatened culture. Mok and Morris suggest that the contrast effect should occur both ways for low-BII individuals, yet to our knowledge, evidence that priming the heritage culture would also threaten the majority culture is nonexistent. In one of their studies, Mok and Morris (2013, Study 1) tested contrastive processes after the heritage culture had been cued, but found no contrast. In a footnote, the researchers raise the possibility of methodological weaknesses in the design of their study. However, it is also possible that low-BII individuals' perception that their heritage culture identity is threatened after having been cued with majority culture is uniquely tied to experiences of discrimination in the majority culture (and that a similar threat might simply not exist in the other direction).

Supportive of our view that contrastive frame switching should be understood from discrimination and exclusion from the majority context particularly, is the finding that low BII (i.e., low perceived harmony and blendedness of the two cultures) is tied to strained intergroup relations (e.g., discrimination). This seems to be the context in which majority culture is perceived to threaten the heritage culture. Individual differences in cultural frame switching can be understood, then, from the context in which BII is formed. As Cheng et al. (2014, p. 283, emphasis in original) concluded: "*Both* high and low BII biculturals engage in cultural frame switching; they both possess two cultural frames of reference and can switch their

[psychological processes] in response to cultural cues. However, high and low BIIs tend to respond to cultural cues in different ways, with high BIIs often engaging in assimilative cultural frame switching and low BIIs often engaging in contrastive cultural frame switching.”

Putting the elements together, these studies yield interesting insights into the relationship between explicit and implicit acculturation. Even when immigrant minorities have the “cultural competence” (LaFromboise et al., 1993) or when they have “two minds” (Hong et al., 2000), they may not always act, think, or feel in ways that would be most adaptive in the majority cultural context; if they are low on BII, they are likely to act, think, or feel in ways that are right by their heritage minority culture, when navigating the majority culture. Under circumstances of discrimination, exclusion, and troubled intergroup relations, minority individuals are less likely to behave in ways that reveal an implicit affiliation with the majority culture. Therefore, an unfavorable immigration context is very likely to foster psychological responses that impede minority individuals’ successful navigation of the majority context. Clearly, the relationships among cultural context, explicit acculturation, and implicit acculturation deserve more attention, as they will teach us how, and under what circumstances, immigrant minorities do well.

Explicit affiliation does not need to precede implicit affiliation. It is possible that implicit affiliation comes first. For instance, it is possible that feeling as the majority (heritage minority) culture does is the basis for cultural identification. This would be consistent with a literature on couples and groups, showing that similarity in attitudes, personality, and emotions is associated with relationship satisfaction and group identification (Anderson, Keltner, & John, 2003; Barsade, 2002; Delvaux, Meeussen, & Mesquita, 2015; Gonzaga, Campos, & Bradbury, 2007), respectively. It is possible that, under some circumstances, shifts in the patterns of feeling, thinking, and acting make minority individuals feel more part of the majority culture, and are an incentive to share majority customs and traditions.

CONCLUSION

In this chapter, we have outlined the cultural psychology of acculturation. We propose to extend the range of phenomena that traditionally have been studied by acculturation psychology, and to ask the open question: How do psychological processes change, when individuals engage in new cultural contexts? A cultural psychology of acculturation goes beyond studying immigrant minorities' explicit positioning toward the heritage and majority culture, and even beyond their cultural identity. It assumes that acculturation may occur with respect to all psychological processes that are culturally constituted, even processes that have not traditionally been part of acculturation research, such as emotions and personality.

No Privileged Domain

Acculturation may take place in all, or in some, psychological domains. Together, changes in the various psychological domains constitute psychological acculturation. No single process is privileged, and as Schwartz et al. (2010) noted: "The construct [of acculturation] should be labeled appropriately—such as 'behavioral acculturation,' 'value acculturation,' or 'identity-based acculturation' " (p. 244) because "changes in one dimension of acculturation may not mean that other dimensions are changing at the same rate or in the same direction, and the fact that one dimension is changing does not guarantee that others will change as well" (pp. 245–246; see also Birman, 1994; Dere et al., 2010; Keefe & Padilla, 1987; LaFromboise et al., 1993; Padilla, 1980; Phinney & Flores, 2002; Schwartz, Montgomery, & Briones, 2006; Snauwaert, Soenens, Vanbeselaere, & Boen, 2003; Szapocznik & Kurtines, 1980). Although acculturation can be studied separately for different psychological domains, the ultimate goal of acculturation research should be to gain an understanding of the temporal and causal dynamics between changes in different domains of cultural affiliation.

Implicit Cultural Affiliation

This chapter highlights the role of implicit acculturation, which traditional acculturation models neglected. Research addressing implicit cultural affiliation has taken various forms. Some studies show that exposure to

majority culture predicts improved fit with majority culture psychological tendencies. Immigrant minorities over time (or across generations) acquire the psychological responses that are typically found in the majority culture. Our own research on emotional acculturation is an example (e.g., De Leersnyder et al., 2011).

A second type of research on implicit acculturation that used a frame-switching paradigm showed that, on average, biculturals primed with the heritage culture show psychological tendencies that are typical of that culture, and biculturals primed with majority culture show psychological tendencies commonly found in the majority culture (e.g., De Leersnyder & Mesquita, 2014). The research is important in that it shows that acquisition of majority culture psychological tendencies does not need to come at the expense of heritage culture psychological processes. It also suggests that, on average, immigrant minorities are capable of flexibly regulating their psychological responses to fit the immediate cultural context. Frame-switching studies, however, are informative about neither the process of acquisition of new psychological responses nor individual differences in the ability to adapt the psychological processes to the cultural context.

Research on BII has advanced our understanding of individual differences in frame switching (Benet-Martínez & Haritatos, 2005). Whereas individuals scoring high on the BII scale assimilated to the salient majority culture context, individuals scoring low responded with heritage culture responses when primed with the majority culture. Low-BII individuals experience conflict between their cultures, and contrastive priming can be understood as a way of protecting the heritage culture identity when it is perceived to be challenged by the majority culture.

However, it is not known whether frame switching is the norm in immigrant minorities. In early work, LaFromboise et al. (1993) suggested several different ways in which biculturals could manage the “cultural competencies” of their different cultures, one of which was alternation, for which frame-switching studies provide evidence. But another was “fusion,” which means new psychological tendencies emerge that integrate elements from both cultures. Research on bilingualism finds that first-language competencies may shape second-language competencies and, conversely, that acquisition of a second language may change one’s sensibilities in the native language (Pavlenko, 2014; Dewaele, 2010). Analogously, the

psychological effects of living in the majority culture may depend on earlier learning in the first or native culture. At this point, our insights into these processes are extremely limited.

What Are the Underlying Processes?

Very little is known about the processes linking cultural exposure with changes in either implicit or explicit cultural affiliation; neither do we have information about the processes linking these acculturative changes to immigrant minorities' well-being. Sure enough, the term "acculturation process" has been used in the literature, but it refers to the correlation between either certain antecedents and acculturative changes or acculturative changes and well-being. As an example of the former, several studies have shown that there is "intergenerational transmission" of perceived discrimination, cultural identity, and values, such that parents and children are similar in these domains (Phalet & Schönplflug, 2001). While the finding of similarity between parents and children is indeed suggestive of intergenerational transmission, the process itself has hardly been specified.

Studying these processes would mean studying the different ways in which minorities' cultural affiliations, both explicit and implicit, change through minority engagement in the majority culture. Several mechanisms may be involved. First, immigrant minorities are likely to imitate majority responses (and vice versa); majority responses would therefore serve as models. Modeling is an important process of infant and child learning (e.g., Eisenberg, Cumberland, & Spinrad, 1998); it is also thought to play a prominent role in cultural learning (Boyd & Richerson, 1996; Caldwell & Millen, 2009; Tomasello, Kruger, & Ratner, 1993). One question would be: Under what conditions do immigrant minorities imitate the behavior of majorities, given that imitation is a selective process that is most likely to be operative when there is a connection between individuals (Hatfield, Cacioppo, & Rapson, 1994; Lakin, Chartrand, & Arkin, 2008)?

A second type of mechanisms involve learning from the perceived consequences of behavior. It is possible that immigrant minorities learn from experience or from observing other people (sometimes referred to as

“emulation”; Tomasello, 2010) the types of feelings, thoughts, and acts that are rewarding in a given cultural context. The reward may consist of social approval and friendship, of being taken seriously and having job success, and of being able to convey one’s needs and navigate cultural institutions. In all these cases, having experienced, firsthand or secondhand, how to behave in ways that work within the context may lead to psychological changes. Immigrant minorities must have had the experience (even the vicarious experience) of a behavior being rewarded, to adopt it. And in the case of observational learning, they must see majority experiences as relevant to themselves. It is possible that in less inclusive environments, immigrant minority individuals do not believe that acting like the majority will get them similar rewards (and they may be right), in which case, emulation is less effective in bringing about psychological change.

Third, communication between immigrant minorities and majorities may lead to psychological change if it leads to the intercultural negotiation and convergence of meaning making, a process described in psycholinguistic work on the convergence of meaning (e.g., Clark & Wilkes-Gibbs, 1986). During interactions, immigrant minority and majority individuals come to shared understandings of their social environment by finding a mutually recognizable interpretation of the world. Again, very little is known about the processes by which this happens.

Future research should study the processes of modeling, experience-based and observational learning, and the convergence of meaning. Insight into the mechanisms involved should provide insight into the dynamic and temporal unfolding of acculturation, but it will also inform interventions that may help the millions of immigrant minorities have a good life in their cultures of settlement.

Context Is Everything

The cultural-psychological approach ties in with work by other acculturation researchers (e.g., Bourhis et al., 1997; Brown & Zagefka, 2011; Phalet & Kosiç, 2006) that shows how cultural context shapes acculturation. For instance, biculturalism or integration attitudes are more likely to develop in contexts that are welcoming, but segregation is more common when

minorities live a life of discrimination and exclusion. Perhaps more unique to the cultural-psychological perspective is the finding that the most *adaptive* psychological responses differ by context. Whereas bicultural identity is adaptive when the majority favors cultural pluralism (Nguyen & Benet-Martínez, 2013), segregation and assimilation seem to be more beneficial when the majority context is reticent about diversity, possibly because these latter strategies protect minorities against majority rejection (Baysu et al., 2011). Minority acculturation strategies are most beneficial when they fit the expectations and affordances of the majority cultural context.

Research on the role of the larger sociocultural context in *implicit* acculturation is scarce; the exception is research on the role of BII in frame switching, which involves fully bicultural individuals. Once biculturals have acquired cultural competencies in both cultures, a hostile or hierarchical intergroup climate appears to increase the likelihood that biculturals are contrastive in response to being cued by the majority context. We know much less about the influence a hostile or hierarchical intergroup climate has on the process of acculturation itself, that is, the process toward being fully competent in two cultures. It is possible that hostile or hierarchical intergroup climates slow down the changes in implicit affiliation with the majority culture or prevent them from happening altogether. In a similar way, we lack knowledge about the consequences of implicit acculturation to well-being, and on the role of context therein. It is conceivable, for instance, that identification or emotional acculturation is only beneficial when the context is inclusive to begin with: Some degree of acceptance may be necessary before emotional similarity can make a difference in interethnic interaction.

Future research on acculturation should also take into account that many of the contexts we encounter are multicultural. Immigrant minorities are likely to interact with people from different ethnic backgrounds within the same setting (Doucerain et al., 2013) and to speak different languages (Dewaele, 2010). The majority culture may not always be the standard of acculturation, as increasingly many immigrant minorities live in “superdiverse” environments (Meissner & Vertovec, 2015).

Acculturation Research Informs Cultural Psychology

Importantly, we found that acculturation is situated: The extent to which immigrant minorities adopt majority psychological tendencies varies across situational contexts. Both explicit and implicit cultural affiliation have been found to differ by cultural setting. Differences in acculturation strategies were found for private versus public settings (Arends-Tóth & Van de Vijver, 2003), and emotional acculturation differed between (heritage culture) home and (majority culture) work settings (De Leersnyder et al., 2015). Cultural frame switching or alternating may be observed for different contexts, but we know it can also be cued by the language of interaction or the current interaction partner (Dewaele, 2010; Pavlenko, 2014).

The situated nature of acculturation may be taken as a model for cultural psychologists to think about feelings, cognition, and action *generally*. It is possible that each of us flexibly moves between different settings, such as home, work, friends. We may all learn situation-specific traits, selves, emotions, thoughts, and acts (Mesquita, Barrett, & Smith, 2010; Coşkan, Phalet, Güngör, & Mesquita, 2016), and our psychological responses may always be prompted in response to situational cues and fit the demands of the specific context. Frames of meaning vary (if only slightly) between one situation and the next, even within a culture; but this is all the more true for people who move between cultures.

NOTES

1. Acculturation may also happen for majority members whose daily interactions with minority friends, colleagues, or romantic partners bring them in contact with other cultures. Moreover, economic globalization and cultural exchange are conditions for acculturation as well. However, in this chapter, we focus on minority acculturation, in part because this is the focus of existing research.

2. When calculating the emotional fit for majority individuals, we omitted their emotional profile from the majority average. Thus, we prevented conflation of emotional fit scores for majority individuals.

3. The emotional fit of immigrant minorities was smaller for home situations than for work situations. This renders another explanation of the emotional acculturation data—that emotional fit of immigrant minorities is lower simply because they do not understand the majority culture situations—less likely. In fact, emotional fit with majority culture was lower at home, where the heritage culture still plays a big role.

CHAPTER 20

Making Meaning

A Culture-as-Situated-Cognition Approach to the Consequences of Cultural Fluency and Disfluency

Daphna Oyserman and Veronica X. Yan

We describe a culture-as-situated-cognition (CSC) approach to understanding how culture helps people get through their everyday lives. CSC starts with the idea that people have available in memory an array of culturally rooted associative knowledge networks: Some networks include content, procedures, and goals related to overarching themes of individualism, collectivism, and honor (cultural mindsets). Others include knowledge about various aspects of everyday life (e.g., what breakfast entails). In their own culture, people mostly experience situations that match their (implicit) expectations, so that not much thought is needed. When these (implicit) expectations are violated, something feels awry and closer consideration is warranted. The terms “cultural fluency” and “cultural disfluency” capture both the cultural and the metacognitive (thinking about thinking) aspects of this process. Cultural (dis)fluency is the result of the interface between what observers’ cultural expertise leads them to (implicitly) expect, what they actually observe, and the meaning they draw from their metacognitive experience of ease or difficulty. Downstream consequences of these interpretations depend on what people infer is the source of experienced ease or difficulty—the situation or themselves. CSC spotlights an underappreciated aspect of culture—that culture allows people to get through their days without much thought and while also alerting them when attention might be warranted.

Cultures are dynamic and changing, yet at any point in time, they are substantive. As a result, being a part of a culture means knowing what to

expect in everyday life as it unfolds. We describe a culture-as-situated-cognition approach to understanding how culture helps people get through their everyday lives, conceptualizing culture as a sense-making framework that includes the practices, meanings, structures, and values shared by members of a group in a particular time and place. Culture-as-situated-cognition theory starts with the idea that people have available in memory an array of culturally rooted associative knowledge networks, only some of which are activated in any given context. Activated associative knowledge networks shape expectations and have downstream consequences for thinking, feeling, and doing. Some of these associative knowledge networks include content, procedures, and goals related to overarching themes of individualism, collectivism, and honor (cultural mindsets); others include knowledge about various aspects of everyday life (e.g., what weddings, breakfasts, and holidays entail).

Culture supports sense making by influencing the content of the automatic predictions people make as to what will happen next in any given situation. Predictions emerge from activated culturally rooted associative knowledge networks and are automatically checked against an error detection system. This yields a metacognitive experience of ease (fluency) when observation matches culturally rooted prediction and of difficulty (disfluency) when an error is detected (mismatch). People do not have to interpret their metacognitive experiences but often do.

In their own culture, people mostly experience situations that match their (implicit) expectations.¹ The ensuing metacognitive experience of ease implies that not much thought is needed; however, situations vary, and sometimes these (implicit) expectations are violated. When that happens, the ensuing metacognitive experience is one of difficulty. Something feels awry, and closer consideration is warranted. The terms “cultural fluency” and “cultural disfluency” capture both the cultural and the metacognitive (thinking about thinking) aspects of this process.

Cultural fluency and disfluency are the result of the interface between what observers’ cultural expertise leads them to (implicitly) expect, what they actually observe, and the meaning they draw from their ensuing metacognitive experience of ease when observation and expectation match or difficulty when observations violate expectations. Interpretation is the result of drawing meaning from the metacognitive experience of *ease* when

culturally rooted implicit expectations match observations and from the metacognitive experience of *difficulty* when culturally rooted implicit expectations are violated (or do not match observations). Downstream consequences for thinking, feeling, and doing depend on whether people infer that the source of experienced ease or difficulty is external (in the situation) or internal (themselves). Interpretation does not require explicit self-reportable thoughts or emotions such as “This is not traditional!” or “This is not similar to what I do!” or “I don’t feel happy!” or “I feel anxious!” or “I feel angry!” Taking a culture-as-situated-cognition approach spotlights an underappreciated aspect of culture, which is that culture allows people to get through their days without much thought, while also alerting them when attention might be warranted.

If culturally rooted expectations match reality, things have unfolded as expected, implying “All’s right with the world.” The metacognitive experience here is of ease: There is no problem signal, so there is no need to think more. In contrast, mismatches between culturally rooted expectations and observed reality are unexpected and require explanation. The metacognitive experience here is of difficulty: Things have not unfolded as implicitly expected, and this signals a possible problem. Mismatches require considering why expectations were wrong. What makes something feel easy or feel difficult is not the thing itself, but its fit with culturally rooted and culturally bound expectations—hence, particular stimuli can be experienced as fluent or disfluent because of the cultural knowledge brought to bear. Experiencing confirmation (expectation–observation match) or violation (expectation–observation mismatch) requires having the cultural expertise to know implicitly what to expect and is a “metacognitive” experience, a feeling about thinking. This experience of fluency when there is a match and of disfluency when there is a mismatch is often interpreted; as we demonstrate in this chapter, how these metacognitive experiences are likely to be interpreted matters.

That each societal culture differs in its practices, traditions, and ways of doing things is not a particularly novel insight, nor is it perhaps particularly surprising to say that sometimes the unexpected happens. However, as detailed in this chapter, buried in these seemingly mundane and taken-for-granted aspects of culture and everyday life is a novel insight about the downstream consequences of having cultural expertise for thinking, feeling,

and doing. We divide our chapter into sections, each highlighting a piece along the way to understanding the current state of knowledge about the cognitive and metacognitive implications of cultural fluency and disfluency for thinking, feeling, and doing.

First, we outline our general framework for understanding culture—culture-as-situated cognition theory. We define what we mean by culture and cultural expertise within this theoretical framework. Second, we provide an overview of the neural basis of cultural fluency and disfluency responses by describing the error detection system. Third, we describe how conditions of cultural fluency or disfluency arise and how researchers manipulate them in the laboratory to understand processes that occur in the world outside the laboratory. Fourth, we discuss downstream consequences of interpreting experiences of cultural fluency and disfluency on thinking, feeling, and doing. We provide examples of consequences in each domain. For “thinking,” or cognitive processing, we articulate consequences for simple and complex cognitive task performance and for associative and systematic reasoning. For “feeling,” we focus on feelings as informative—as providing cues as to whether all’s right with the world or not. We articulate consequences for experienced inherence and essentialism, as well as possible consequences for well-being and for momentary affective responses. For “doing,” or behavioral responses, we articulate responses to persuasive messages and consequences for engagement in mindless as compared to mindful behaviors. Fifth, we provide a summary overview.

CULTURE-AS-SITUATED-COGNITION THEORY

What Does “Situated” Cognition Mean?

Situated cognition focuses on “thinking in the world”—the impact of social contexts on thinking and action (Meier, Schnall, Schwarz, & Bargh, 2012; S. Fiske & Taylor, 2013; Schwarz, 2007; Cesario, Grant, & Higgins, 2004). Situated approaches suggest that “thinking is for doing,” with the implication that people are sensitive to their immediate environment, use the subset of all their knowledge that is accessible in the moment, and interpret what comes to mind in light of contextual demands (S. Fiske & Taylor, 2013;

Bless, Schwarz, & Wänke, 2003). What a situation implies depends on how one thinks about it—what comes to mind to make sense of it.

What comes to mind may be knowledge—semantic content (Srull & Wyer, 1979), goals (Förster, Liberman, & Friedman, 2007), and procedures (Oyserman & Lee, 2008; Schwarz, 2011; Wyer & Xu, 2010)—or metacognitive experiences of ease or difficulty while thinking about content, goals, and procedures (Bless & Schwarz, 2010). Each yields a signal as to how to process information to make sense of experience and hence how to respond. Unless they have reason to exclude it, people tend to include accessible knowledge and metacognitive experience of ease (fluency) or difficulty (disfluency) in their judgments (Bless & Schwarz, 2010).

Although people are sensitive to what comes to mind and to their experience of thinking about what is on their minds, they are not sensitive to the specific source of accessible information or accessible feelings of ease and difficulty (Schwarz, 2005, 2007). Hence, information and feelings may carry over to inform judgment on subsequent tasks, even if the information or feelings on one's mind are not relevant to the task at hand (Bless & Schwarz, 2010; Schwarz & Clore, 1983). Moreover, in each situation, the interpretive lens individuals bring to bear mediates the effects of ease and difficulty on what is understood (Alter & Oppenheimer, 2009; Briñol, Petty, & Tormala, 2006a; Schwarz, 2004). An experience of fluency or disfluency may imply something about the outside world or something about oneself (Alter & Oppenheimer, 2009; Fisher & Oyserman, 2017; Reber & Schwarz, 1999; Schwarz et al., 1991; Schwarz, 1994).

Culture-as-situated-cognition theory (Oyserman & Lee, 2007; Oyserman, 2011, 2017) starts with the assumption that humans live in cultures, that cultures address universal demands of living with others, and that people make sense of what the immediate context seems to imply, using a cultural lens. By emphasizing immediate context, culture-as-situated-cognition theory deemphasizes speculation about distal causation of current between-group differences. By focusing on immediate context, culture-as-situated-cognition theory reconciles literature documenting what appear to be chronic cross-cultural differences with literature documenting situated flexibility (Oyserman, 2016). This approach highlights two largely overlooked points: First, *culture* can be represented as a set of associative knowledge networks. People have access to and can use multiple culturally

rooted associative knowledge networks, depending on which is cued and seems relevant in context. These knowledge networks include both cultural mindsets (content, procedures, and goals related to overarching themes of individualism, collectivism, and honor) and specific culturally rooted knowledge about how things work (e.g., what breakfast entails). Second, these culturally rooted associative knowledge networks provide mental models, affording people the *cultural expertise* to predict how situations should unfold. Therefore, what matters for meaning making is the cultural mindset accessible in the moment. Accessible mindsets yield culturally rooted expectations. If observation implies mismatch with expectations, this requires attention to understand why. In this chapter, we focus on this latter prediction. To understand how, we first define what we mean by culture and cultural expertise.

Defining Culture within Culture-as-Situated-Cognition Theory

As a starting point, culture-as-situated-cognition theory assumes that human culture developed from the survival necessity of connecting with others and adapting to group living (Boyd & Richerson, 1988; D. Cohen, 2001; Haidle et al., 2015; Oyserman, 2017; Schwartz, 1992). Living together requires that people coordinate and organize their relationships, clarify group boundaries, and notice and reward innovation, so that they can imitate or exploit innovation as it occurs and otherwise fit in, and know from whom and to whom they owe allegiance (Boyd & Richerson, 2005; Kurzban & Neuberg, 2005; Oyserman, 2011; Schwartz & Bardi, 2001). Though the basic problems of group living must be addressed, human-made cultural solutions may put more emphasis on one or another aspect of these, depending on the ecological niche. In each society, practices evolve to create “good enough” ways to regulate relationships, specify group boundaries and what to do about them, and spotlight when innovation is acceptable or valued (D. Cohen, 2001; Boyd & Richerson, 2005; Kurzban & Neuberg, 2005; Oyserman, 2012, 2017; Schwartz, 1992). Coordinating and organizing relationships, and noticing and rewarding innovation, require “social tuning”—sensitivity to others’ perspectives and “self-regulation”—the ability

to control the focus of one's attention (Chiu et al., 2015; Oyserman, 2017; Shteynberg, 2015). Indeed, people are sensitive to cues about when to imitate (fit in), when to innovate (Chiu & Hong, [Chapter 26](#), this volume; Clegg & Legare, 2016; Legare & Nielsen, 2015), and when group boundaries matter (Boyd, Richerson, & Henrich, 2011; Haidle et al., 2015).

Solutions are “good enough” rather than optimal. However, once developed, they become “sticky” by virtue of being the ways “we” do things —“our” structures, practices, norms, and values (D. Cohen, 2001). Taken together, this set of good-enough solutions forms culture, the particular set of practices people in a particular society, time, and place share. Once developed, cultural solutions permeate all aspects of behavior, constrain and enable perception and reasoning, and provide a shared blueprint or outline for meaning making across a variety of situations (Chiu, Gelfand, Yamagishi, Shteynberg, & Wan, 2010; Masuda, Russell, Li, & Lee, [Chapter 8](#), this volume; Nisbett & Noranzayan, 2002; Oyserman, 2017; Shteynberg, Gelfand, & Kim, 2009; Shweder & LeVine, 1984; Triandis, 1972, 2007). In this way, culture is in part a set of associative knowledge networks, tacit operating codes, or meaning-making frameworks through which people make sense of their world (Geertz, 1973) and understand what they want, and how they go about getting it (Bond, 2002; A. Fiske, 2002; Kitayama & Markus, 1994; Sanchez-Burks, Nisbett, & Ybarra, 2000; Swidler, 1986). As a result, culturally appropriate situations seem right and generate an experience of fluency; culturally inappropriate situations—even when the violation is subtle—seem wrong or off-key and generate an experience of disfluency.

Cultural Expertise and Culture-as-Situated-Cognition

From a culture-as-situated-cognition perspective, “cultural expertise”—knowing how things work in one's everyday life—is not reducible to whether a culture is focused comparatively more or less on individualism, collectivism, or honor (Oyserman, 2017). Cultural expertise provides a way of knowing what to expect in everyday situations, so the world feels sensible and orderly. This includes but is not limited to knowing when uniqueness is good and valued, how to connect, and which aspects of reputation matter.

People gain cultural expertise simply by being socialized in a society; beyond that, moving to or living in a society for a length of time yields varying degrees of this expertise (Leung & Koh, [Chapter 21](#), this volume; Morris, Chiu, & Liu, 2015; Morris, Fincher, & Savani, [Chapter 18](#), and Mesquita, De Leersnyder, & Jasini, [Chapter 19](#), this volume). Whatever way it is acquired, people experience cultural expertise as the simple and obvious way things are, as can be seen in the following examples: A beaming bride walks down the aisle toward her soon-to-be husband. What color is her dress? Breakfast is being prepared. Will there be cucumbers? For Americans, “white” and “no,” respectively, likely come to mind easily as the obvious and natural answers—but note that knowing what to expect requires availability of American cultural expertise—what Americans in America have without noticing it. These culturally fluent answers “go without saying.” They feel so obvious that posing the bridal dress or cucumber breakfast questions may feel like riddles, highlighting the possibility that the questioner means something other than the obvious. That is what makes the question “Who is buried in Grant’s tomb?” a funny riddle—the answer “Grant” is so obvious that people are often stumped, assuming that the question would not be asked if the answer really was “Mr. Grant.”

This experience—of naturalness, obviousness, and ease—is neither reserved for Americans nor is it only applicable to these answers. Answer content—what the easy, obvious, and natural answers are—may change across cultures, as well as across time in a culture. Currently, wedding dresses might be red, white, or pink in Chinese culture, and cucumbers could easily be on the breakfast menu in Israeli culture. Expectation changes across cultures, but the feeling of obviousness does not. Knowing the culture—the values, norms, practices, and ways of being in a particular time and place—means that the answers spring to mind easily and feel obvious.

Note that despite this obviousness, variability exists. Consider our breakfast example. American breakfasts usually have no vegetables at all but, of course, they can and sometimes do. For example, some omelets include cooked vegetables. Raw vegetables—cucumbers, tomatoes are common in Israeli breakfasts, but cooked ones are not. But, cooked vegetables are also possible, for example, a fancy Israeli breakfast could be a base of cooked vegetables with an egg on top. We focus on the consequences of both obviousness and variability.

Activating Cultural Expertise via Culturally Rooted Associative Knowledge Networks

Distinguishing Availability and Endorsement

Having cultural expertise entails knowing how things work. Using the language of culture-as-situated-cognition theory, cultural expertise entails *availability* (not necessarily endorsement) of culturally rooted associative knowledge networks. Cultural expertise does not necessarily imply that a person agrees with or acts on cultural norms, practices, meanings, or values. That a culturally rooted associative knowledge network is available does not mean that its contents are *endorsed*. People might agree or disagree with their culture's practices, its values, meanings or structures (e.g., Morris et al., 2015; Oyserman, Kemmelmeier, & Coon, 2002b). Yet by virtue of being socialized in a culture, a set of practices, values, meanings, and structures is available, part of culturally rooted associative knowledge networks located in one's memory. This availability allows people to make sense of their world and predict how situations will unfold. Thinking feels easy and fluent when situations seem to match one's cultural expertise and unfold following one's implicit or explicit cultural scripts.

Distinguishing Availability and Accessibility

Culturally rooted cues are ubiquitous. However, in natural settings, it is often difficult to distinguish availability and accessibility. "Availability" means that something is in memory. "Accessibility" means that it is on the mind in the moment. Does finding a null effect mean that something is not available in memory, or does it mean that it may be in memory but is not on the mind in the moment?

Which culturally rooted associative knowledge network is activated at any given point in time depends on a number of factors—a network is more likely to be activated if it has been frequently activated, if it has recently been activated, and if it seems relevant to one's immediate environment (Bargh, 1994; Collins & Loftus, 1975). Because "thinking is for doing" (S. Fiske, 1992), which details are processed as meaningful cues is a function of cultural expertise and, in particular, what is culturally and situationally

relevant in that moment. Some cues are likely to be peripherally associated with a number of knowledge networks and more centrally located in other knowledge networks. For example, from a Western cultural lens, seeing lights strung up in December may activate a Christmas knowledge network; seeing a nativity scene may activate this knowledge network no matter the time of year. The birth of Christ is central to a propositional understanding of what Christmas is, whereas lights are merely associated with the connected practices (e.g., Gawronski & Bodenhausen, 2007, 2011). Both propositional understanding and associated practices may cue cultural fluency and disfluency.

Whether a given cue activates a particular knowledge network depends on cultural expertise: Seeing a string of lights in December will only activate the “Christmas” associative knowledge network if the person already holds a “Christmas” associative knowledge network and that network includes “a string of lights.” The “Christmas” associative knowledge network is more likely to be on the mind in December (around Christmastime) and when Christmas-related features such as green and red paper-wrapped gifts are in the immediate environment. Whether Christmas carries with it an individualistic (“What do I want for Christmas?”), collectivistic (“Do my gifts meet my obligations?”), or honor (“Are other people sending me cards and gifts that demonstrate their respect for me?”) mindset depends in part on immediate cues. We represent this process graphically in the first two panels of [Figure 20.1](#) by showing how a cue (e.g., a string of lights) might cue a culturally rooted associative knowledge network such as Christmas, and in this way automatically trigger a prediction: *Gifts will be exchanged*. Not all of the many cues in a context receive equal attention—thinking is for doing after all, so whether people attend to the lights should be a function of what else is happening. One key feature of this process is that it is probabilistic rather than deterministic. Cues will only probabilistically activate certain associative knowledge networks. In our example, the string of lights is more likely to activate a “Christmas” associative knowledge network in December while at the shopping mall than in October at a restaurant, or in July while at the beach. The smaller nodes in the middle panel of [Figure 20.1](#) represent these other possible associative knowledge networks.

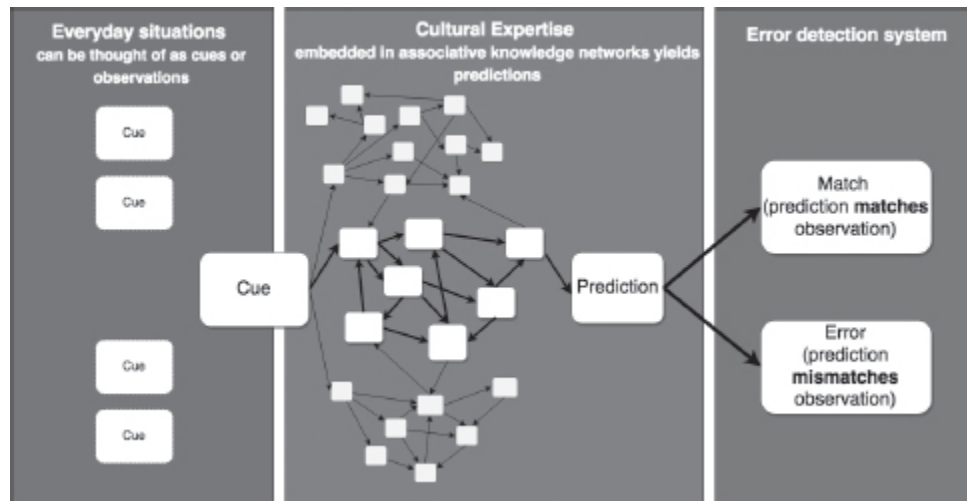

FIGURE 20.1. From cues to prediction. Features, or cues, in the immediate situation (left panel) interact with cultural expertise to activate an associative knowledge network (middle panel). This activated network in turn produces a prediction (middle panel), which is then compared against the observed situation (right panel). Predictions generated from the activated associative knowledge networks may either match or mismatch the observed situation. Adapted from Oyserman (2017). Color version is provided at <http://doi.org/cmn9>.

THE ERROR DETECTION SYSTEM

As documented in [Figure 20.1](#), situations activate culturally rooted associative knowledge networks that yield predictions (“This is Christmas, there will be gifts!”). However, making a (implicit or explicit) prediction is not the end of the process. Many theories predict that people see what they expect or are motivated to see (e.g., Bruner, 1957; Bruner & Goodman, 1947; Merton, 1948; Snyder, 1984; Wason, 1960). Yet no matter how motivated they are to find what they expect to find, and to observe what they expected to observe, people’s expectations are sometimes violated. Life unfolds, and it does not always unfold as one’s activated culturally rooted associative knowledge networks would lead one to expect that it would unfold. Predictions do not always match observations.

In this section, we describe the error detection system, because the process we are describing is compatible with neural predictions models and the concept of the “predictive brain.” Hence, the implication is that the culture-based prediction process is likely to be a human universal (Bar, 2009; Bubic, von Cramon, & Schubotz, 2010). The notion of the predictive

brain highlights the central importance of predictive processing. The brain is designed to process information not only to make sense of the past and present but also to be ready for future states of the body and the environment. The brain uses a “proactive link” (Bar, 2009), comparing novel inputs to existing, familiar representations. Once a “good enough” analogy for the novel input is found, associated representations are rapidly activated, presensitizing the related representations that are most likely to occur—these presensitized representations are called “expectations” in everyday language.

Many brain regions and neural networks are involved in computation and encoding of prediction errors (Bubic et al., 2010) across a wide range of domains (motor, perceptual, cognitive, and motivational control and learning; den Ouden, Kok, & De Lange, 2012; Friston, 2005). Prediction generation and error detection testing are found at all levels of the brain and considered crucial for driving both low-level neural processes and high-level behaviors (e.g., social cognition). At the lower perceptual level, for example, predictions facilitate rapid interpretation and disambiguation of noisy or ambiguous inputs (Kersten & Yuille, 2003; Sterzer, Frith, & Petrovic, 2008). At a higher cognitive level, for example, the predictive brain underlies person perception—the mirroring system (Rizzolatti & Craighero, 2004) has been implicated in ‘social tuning,’ people’s capacity to form mental representations of others and to infer their goals (Brown & Brüne, 2012; Kilner, Friston, & Frith, 2007; Saygin, Chaminade, Ishiguro, Driver, & Frith, 2012).

To improve calibration and minimize future potentially costly surprises, the prediction system receives continuous feedback as to whether predictions match or mismatch observations. Signal error is low when a prediction matches observation—if all is as expected, then one can save energy by limiting attention to the expected situation and therefore reserve resources to attend to novelties (Bar, 2009; Friston & Stephan, 2007; Schultz & Dickinson, 2000). Matches increase certainty of future prediction. Mismatches (prediction errors) reduce certainty of future prediction and signal that there is something to be learned or that something in the environment has changed (Friston & Stephan, 2007; Rescorla & Wagner, 1972). Error signals do not provide an answer as to what has changed or what is to be learned, but they do signal that attention is needed, resulting in

a shift from lower to higher cortical levels to facilitate the updating of predictions (e.g., Bar, 2009; Fletcher & Frith, 2009; Friston, 2005; Schultz, Dayan, & Montague, 1997). It is as if error signals send a report: “Something is wrong, but I do not know what it is.”

FROM ERROR DETECTION AND CULTURAL EXPERTISE TO CULTURAL FLUENCY AND DISFLUENCY

From a culture-as-situated-cognition perspective, predictions are those things that are culturally expected, because they are part of culturally rooted associative knowledge networks (Oyserman, Novin, Flinkenflögel, & Krabbendam, 2014). Prediction errors arise when observation belies these culturally rooted expectations. While predictive brain research has not focused explicitly on culture, culture-as-situated-cognition theory highlights two links: First, as noted earlier, predictions are often drawn from culturally rooted associative knowledge networks. Second, the error detection system emits signals of match or mismatch, and these signals themselves yield a metacognition—an experience of ease (when there is a match) or an experience of difficulty (when there is a mismatch). People do not always interpret these experiences of ease and difficulty, but they often do. To the extent that experiences of ease or difficulty are interpreted as implying something about oneself or the world, these experiences have implications for downstream processing and behaviors that we describe later in the chapter. [Figure 20.2](#) illustrates consequences of match and mismatch between observed reality and the predictions generated from an activated culturally rooted associative knowledge network.

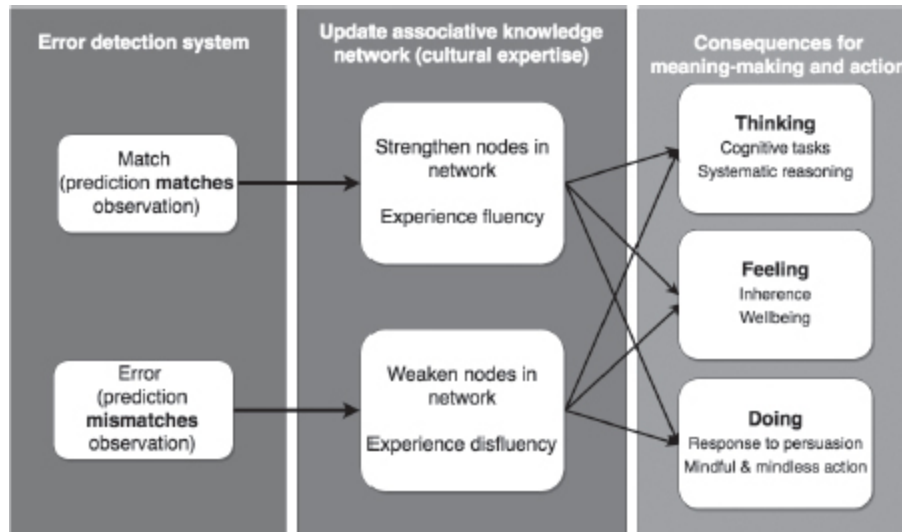

FIGURE 20.2. From predictions to meaning making and action. When predictions from the activated culturally rooted associative knowledge networks are borne out in observations, nodes in the network are strengthened, certainty in understanding the world, and experienced fluency increase—the world is as it should be. Nodes in the network are weakened and experienced uncertainty and disfluency increase when predictions mismatch observations, influencing thinking, feeling, and doing. Adapted with permission from Oyserman (2017). Color version is provided at <http://doi.org/cmn9>.

From Cultural Expertise to Cultural Fluency

Like all associative knowledge networks (Waldmann, 2017), culturally rooted associative knowledge networks are likely to vary in their size, density, and links to other networks, as well as in their activation recency and frequency. What people notice in a situation depends in part on their preexisting associative knowledge networks (Moore, Laiti, & Chelazzi, 2003). When predictions are borne out in observations, the prediction–observation match strengthens the nodes in the network (van Kesteren, Rijpkema, Ruiters, & Fernández, 2010). Certainty in understanding the world increases; the world is as it should be. Matches generate a metacognitive experience of ease (fluency), which can be a source of a subtle affective response: The metacognitive experience of fluency is positive. In contrast, mismatches generate a metacognitive experience of difficulty (disfluency), which can be a source of a subtle negative affective response. The affective response itself is subtle, detectable using physiological measures (e.g., of facial muscles; Winkielman & Cacioppo, 2001). Affective response can carry

over to judgment (Winkielman, Schwarz, Fazendeiro, & Reber, 2003a; Winkielman, Schwarz, Reber, & Fazendeiro, 2003b). Because it is people's cultural expertise that gives rise to experienced ease as a consequence of match to prediction, we term this experience "cultural fluency."

However, events do not always unfold as expected. What if, as shown in [Figure 20.3](#), bottom panel, the beaming bride is wearing a shimmering light green wedding dress and a two-toned veil of shimmering green and purple, matching the groom's purple tuxedo jacket and (not pictured here) the tiered wedding cake is decorated with cogs. The mismatch between predictions and observations contrasts with the expectation of a bride in a white dress, a groom in a black tuxedo ([Figure 20.3](#), top panel), and a tiered white wedding cake with white decoration (not pictured here). Culture-as-situated-cognition theory predicts that mismatch with a culturally rooted expectation yields metacognitive disfluency—thinking is difficult, something went awry, and it is necessary to understand why. This is the case even though context still implies quite clearly that it is a wedding and identifies who the bride and the groom are. Because it is cultural expertise that gives rise to an experience of disfluency as a result of mismatch to prediction, this experience is termed "cultural disfluency."

FIGURE 20.3. Example of culturally fluent (top) and disfluent (bottom) stimuli used in Mourey, Lam, and Oyserman (2015). Color version is provided at <http://doi.org/cmn9>.

Thus, cultural fluency and cultural disfluency are not features of the stimuli alone or of the observer alone. Instead, they are the result of the interaction between what observers' cultural expertise leads them to expect and what they actually observe. Cultural fluency and cultural disfluency arise when predictions made from the automatically spreading activation of a culturally rooted associative knowledge network are borne out (match observation) or are violated (mismatch observation). Over time, repeated exposure to matches between culturally rooted expectation and observation should increase certainty of prediction and increase feelings of inherence—the belief that the world is the way it ought to be (e.g., Salomon & Cimpian, 2014). In contrast, repeated mismatches should reduce certainty and eventually change the associative network itself, including changing certainty about the deep essence of categories (e.g., essentialism, Gelman, 2003). In the next section, we describe how researchers study cultural fluency and disfluency in the laboratory.

Studying Cultural Fluency and Disfluency in the Laboratory

While the insights of cultural fluency and cultural disfluency come from everyday life, for a number of reasons, researchers typically use specific and artificial priming methods rather than rely on descriptions of the natural environment. One important reason is that this method allows researchers to have control over which culturally rooted associative knowledge network is brought to mind (accessible). This allows researchers to distinguish accessibility from availability and to move from description of outcomes to prediction of process models.

For cultural researchers, core questions have to do with the distinction among availability, accessibility, and endorsement. Knowledge that is not available has to be learned; it does not spring forth from brief exposure to a situation (Bargh, 2016; Higgins, 1996). The same is true for the particulars of cultural expertise generally. Features of situations can only bring to mind the culturally rooted knowledge networks a person already has—the ones that are available in memory. A knowledge network that is not available in memory cannot be made accessible by features of the situation—distinguishing availability and accessibility. An accessible knowledge network may influence prediction of how the situation will unfold whether or not the individual endorses the culturally rooted norms, practices, and values this network contains—distinguishing accessibility from endorsement.

Consider the following examples. Priming chronically collectivistic people with an individualistic mindset can shift their accessible mindset to an individualistic one only if an individualistic mindset is available in memory for use. Whether or not people endorse individualism or individualistic values is a separate question from whether or not they know what individualism and individualistic values are. This distinction makes clear that accessibility and endorsement are not the same. Similarly, handing a person a plate with pumpkin and bat decorations in October should not cue “Halloween!” for a person who does not have a Halloween knowledge network available in memory. Without the associative knowledge network of “Halloween,” a plate is just a plate and bats and pumpkins do not carry added meaning when they come together in October. Researchers can

demonstrate effects of activated culturally rooted knowledge networks by controlling what is accessible. Separately, they can ask to what extent these effects are a function of actually endorsing particular values or norms or practices by measuring endorsement and testing its effects.

The logic of priming is that temporarily accessible “on-the-mind” information carries over to the next task, unless something about the situation undermines its relevance (e.g., Bargh & Chartrand, 2000; Bless & Schwarz, 2010; Schwarz, 2007; Srull & Wyer, 1979). Even if people are aware of what is on their minds, they are likely to assume it is on their minds because it is relevant to the task at hand unless they are aware that it is on their minds because the researcher drew their attention to it (Bargh, 2016). Because features of situations should influence how an accessible culturally rooted knowledge network is used, priming is typically accomplished as a two-step process (priming task, test of downstream consequences). In the first step, cultural fluency or disfluency is the consequence (the result of priming); in the second step, cultural fluency or disfluency is treated as the independent variable—the manipulation that affects downstream consequences. This two-step process is useful because it allows researchers to test the effect of accessible information separately from people’s beliefs about what they would or should do. In the context of tests of culture-as-situated-cognition, the priming task brings to mind a culturally rooted associative knowledge network. Increasing accessibility of any specific aspect of the network can do this, including relevant content, procedure, goal or metacognitive interpretation, whether or not it would otherwise have come to mind. The second step for culture researchers is to assess whether the predicted downstream consequences are found.

Much of the research to date has not focused on consequences for cultural fluency and disfluency. Instead, it has focused on other consequences of activating a culturally rooted associative knowledge network at all (Oyserman, 2016, 2017). This research has demonstrated that a wide array of subtle situational cues can “turn on” or elicit individualistic, collectivistic, and honor cultural mindsets (see Oyserman, Coon, & Kemmelmeier, 2002a; Oyserman & Lee, 2008; Novin & Oyserman, 2016). Each cultural mindset may be thought of as a web of interlinking culturally rooted associative knowledge networks, including the specific content, procedures, and goals relevant to the broad cultural themes of

individualism, collectivism, and honor.² While literature to date focuses mostly on cultural mindsets—individualistic, collectivistic, and honor mindsets—there is no reason to assume cultural effects are limited to these mindsets. When a culturally rooted associative knowledge network is brought to mind, it should be available and influence subsequent judgment, unless its relevance is called into question. For example, activating a “Christmas” associative knowledge network might lead to predictions about gifts, parties, seeing Santa Claus, and the colors red and green, as well as the birth of Jesus, nativity scenes, family, religion, and so on. Downstream judgment should be affected by whether observation matches these predictions.

To test this prediction, researchers randomly assign participants to visual or semantic stimuli that match or do not match culturally rooted expectations (e.g., about breakfast, funerals, weddings) using actual cultural products, cards, photographs, or restaurant menus (e.g., Mourey, Lam, & Oyserman, 2015; Lin, Arieli, & Oyserman, 2018). The expectation is that exposure to these cultural products will increase the likelihood that networks of cultural knowledge will be activated and applied to the task at hand. Across studies, stimuli vary in likely centrality to a culturally rooted associative knowledge network. Developing stimuli requires a fine-tuned knowledge of the specifics of a culture, to know what is “right” and what is a bit off-kilter, without being simply wrong or even insulting (e.g., Oyserman, 2011). Stimuli are linked to “our” way of doing things (what to have for breakfast, which dresses brides wear for weddings) and to specific events centrally rooted in “our” religion or origin myths (e.g., Easter for Christians in America, Purim for Jews in Israel, Qing Ming for Chinese in China). For example, Mourey and colleagues (2015) and Lin and colleagues (2018) manipulated the cultural fluency of wedding photographs by manipulating the color of a bridal dress. Participants were asked to rate the quality of photographs from a wedding. The photographs were of equal quality, but in one set the bride wore a white gown (culturally fluent condition; these images were rated as more traditional) and in the other the gown was green or black (culturally disfluent condition; these images were rated as less traditional).

Cultural priming techniques can be used both between and within individuals; that is, researchers can randomly assign the same individuals to

tasks in which different culturally rooted associative knowledge networks are activated. This requires testing changes within a person across time. The alternative is to randomly assign different individuals to tasks in which these culturally rooted associative knowledge networks are activated. This allows comparing individuals at a single point in time. In each case, unless individuals are made aware of why this information has been activated, information from the activated knowledge network should carry over to the next task. Participants should experience ease if the activated knowledge network matches the demands of the task at hand and difficulty if it does not.

CONSEQUENCES OF CULTURAL FLUENCY AND DISFLUENCY

In this section, we describe downstream consequences of experiences of cultural fluency and disfluency for thinking (cognition), feeling (mood, inference, well-being), and doing (responses to persuasion attempts, mindless and mindful behavior or action).

Thinking

Simple and Complex Cognitive Task Performance

Culture-as-situated-cognition theory predicts that people have access to multiple culturally rooted associative knowledge networks that influence meaning making and judgment. Research documents this process across a range of simple and complex cognitive tasks (e.g., Oyserman, 2017). When the activated culturally rooted associative knowledge network includes procedures that match the requirements of the task at hand, performance improves. When the activated culturally rooted associative knowledge network includes procedures that mismatch the requirements of the task at hand, performance is undermined.

While this literature does not use a cultural fluency and disfluency framework, we predict that people use the mental procedures associated with their currently accessible mindset because these procedures feel fluent.

Thus, performance is not a function of which knowledge network is activated or of whether the activated knowledge network is the one that is chronically accessible. Instead, people use the mental procedure that is part of the activated network; whether this helps or undermines performance depends on whether it is the right procedure for the task at hand. If no network is activated, whichever culturally rooted associative knowledge network is more chronically accessible is the one that likely will be on the mind; the mental procedure associated with that knowledge network will be used. From a cultural fluency and disfluency model, the activated mindset yields procedures that feel fluent to use and are hence applied unless people have reason not to use them—for example, if they are explicitly told to use a different procedure.

To illustrate, the literature suggests consequences from cueing an individualistic mindset: People perform better on complex analytic, decontextualizing tasks such as Raven's Progressive Matrices task (Oyserman et al., 2017). They are better at identifying images embedded in a larger picture in a "hidden picture" task (Kühnen, Hannover, & Schubert, 2001). They make fewer mistakes in ignoring irrelevant information in visual and audio Stroop-like tasks (Oyserman, Sorensen, Reber, & Chen, 2009). The literature also suggests consequences from cueing a collectivistic mindset: People perform better on holistic, connecting tasks, such as the keep track task (Oyserman et al., 2017). They are better at recalling contextual (location) information (Oyserman et al., 2009) and at identifying compound letters made up of little letters (a Navon task; Kühnen & Oyserman, 2002). These effects of accessible culturally rooted associative knowledge networks occur regardless of whether participants are from the United States or Asia, even though the cultural mindsets that are chronically active may differ in these countries (Kühnen & Oyserman, 2002; Oyserman & Lee, 2008; Oyserman et al., 2009, 2017).

The pattern of effects in the non-cued mindset control conditions in these studies corroborates the prediction that chronic activation likely varies: In America, control participant performance resembled that of participants in the cued individualistic mindset condition. In Asia, control participant performance resembled that of participants in the cued collectivistic mindset condition. The implication is that without the experimental prime, many Americans would have an individualistic

mindset accessible and many Asians would have a collectivistic mindset accessible. Note that in each of these studies, results depend on people using the primed cultural mindset even if it is not the optimal one for the task at hand. For example, in a task requiring holding category membership in mind, people primed with an individualistic mindset do worse than people primed with a collectivistic mindset (Oyserman et al., 2017). In Hong Kong, control group participants are like collectivistic mindset participants and outperform those in the individualistic mindset condition on this task. In the United States, control group participants are like individualistic mindset participants and the collectivistic mindset participants outperform both groups. When the task requires ignoring surface relationships and using rules, people primed with collectivistic mindsets do worse than people primed with an individualistic mindset (Oyserman et al., 2017). In Hong Kong, control group participants are like collectivistic mindset participants, and the individualistic mindset participants outperform both groups. In the United States, control group participants are like individualistic mindset participants, and both groups outperform participants in the collectivistic mindset condition.

At the same time, studies that do not prime mindset sometimes simply provide instructions that are likely to fit or misfit with chronically accessible mental procedures given the likely cultural mindset. For example, Kitayama, Duffy, Kawamura, and Larsen (2003) did not prime mindset but provided instructions that fit either the likely chronically accessible mindset of American participants or of Japanese participants. They found that people were better at performing a task when the instructions for drawing a line fit what they likely expected given the mental procedures associated with individualistic and collectivistic mindsets. If the draw-a-line task was explained as drawing a line of the same length as one saw before, ignoring the context it was in (a mental procedure entailing pulling apart), Americans did better. If the draw-a-line task was explained as drawing a line that fit the proportion of the line to the box one saw before (a mental procedure relating and connecting), Japanese did better.

We believe that a cultural fluency conclusion can be drawn from this research even though it was not initially framed in terms of cultural fluency and cultural disfluency. Our logic is as follows: Using the mental procedures cued by an accessible cultural mindset feels fluent whether that mindset is

chronically or momentarily accessible. The accessible cultural mindset sets up a prediction that tasks are best solved using the mental procedures in this associative knowledge network. People use the mental procedures that are part of activated knowledge networks even if the mental procedures linked to another culturally rooted associative knowledge network would have been more efficient. Performance is a function of the match between accessible mental procedures and the mental procedures that would be efficient in solving a problem. The culturally fluent mental procedure may or may not be the better one for the task at hand. When no cultural mindset prime is used, people still make automatic predictions as to the mental procedure to use. In tasks such as Kitayama and colleagues' task (2003), the specific instructions either match or mismatch the likely activated mental procedure, and prediction error yields disfluency. The task is experienced as difficult if the expected way to draw a line is not the way the researcher wants it done. In other tasks—such as the Raven's Progressive Matrices or the Keep Track task—the specific instructions (find the correct solution) do not themselves match or mismatch with a mental procedure, and participants are not told which mental procedure to use; in these cases, using the on-the-mind procedure feels fluent whether or not it is the best one to use.

Systematic Reasoning

Culture-as-situated-cognition theory predicts that people will use the accessible culturally rooted associative knowledge network to make automatic predictions about what they observe, and that error detection cues systematic reasoning to unpack the error source. Evidence for this process comes from a number of studies using the cognitive reflection task (CRT; Frederick, 2005), which is a set of questions that have both a gut-based (but incorrect) response and a rule-based (and correct) response. An example of a classic CRT question is: "A ball and a bat together cost \$1.10. The bat costs \$1 more than the ball. How much does the ball cost?" Participants' gut-based response tends to be "\$0.10"; the rule-based correct answer, however, is "\$0.05." The gut response here is "\$1.10 is a dollar more so, $\$1.10 - \$1.00 = \$0.10$ "; the rule here is " $\$1.00 + 2x = \1.10 , $x = \$0.05$."

Hence, the bat costs \$1.05 and the correct answer for the cost of the ball is \$0.05.”

In these studies, cultural fluency and disfluency are primed by having participants experience something that fits or does not fit cultural expectations. For example, the prime might be to read an obituary and choose the best organization of the paragraphs. In the culturally fluent condition, the family is sad, and the deceased is loved and will be missed. In the culturally disfluent condition, the family is not sad, and the deceased was not loved, and the family is relieved to no longer have to deal with this person in their lives. The test is whether reading the disfluent text turned on systematic reasoning and hence changed performance on the next task (the CRT). Across multiple studies using different manipulations of cultural fluency and disfluency, participants in the culturally fluent condition (in which implicit prediction and actual observation likely matched) were less likely to use systematic reasoning than were participants in the culturally disfluent condition. Findings were consistent whether the fluent cue was the color pink (vs. the disfluent black or white) on Valentine’s Day, wedding photographs in which the bridal gown was white (vs. green), a funeral obituary with sad (vs. happy) content (Mourey et al., 2015), or when rule breaking (eating on the metro) rather than benign behavior (reading on the metro) followed furtiveness (Oyserman, 2012). In each case, participants completed a task, whether it was rating the quality of wedding photographs or organizing paragraphs of an obituary. Within the task, they experienced fluent or disfluent elements (the color of the bridal gown, the affect of the obituary). This carried over to the subsequent task. Participants in the culturally fluent condition were more likely to go with their gut than were participants in the culturally disfluent condition.

In this particular task, going with a gut response yielded an incorrect answer. However, readers should not conclude that cultural fluency is always bad for performance. The larger point is that cultural disfluency increases systematic reasoning—using a rule is useful in the CRT task, because a rule applies. But rules do not always apply for real-world problems, and in these cases, a more intuitive, gut-based approach would be better (e.g., Gigerenzer, Todd, & the ABC Group et al., 1999).

Feeling

Mood

Culture-as-situated-cognition theory predicts when cultural fluency and disfluency will occur, and situated cognition studies document effects of fluency on affect (mood). Sad mood can serve as a problem signal, increasing the likelihood of systematic reasoning, whereas happy mood serves as a signal that all is fine and increases the likelihood of associative reasoning (Alter, Oppenheimer, Epley, & Eyre, 2007; Schwarz, 2002). The implication is that cultural fluency and disfluency might influence mood, with mood influencing downstream cognitive processing. Research to date has not found such a connection, at least at the level of self-reported mood obtained by the Positive and Negative Affect Scale (PANAS; Thompson, 2007). Across five experiments, Mourey and colleagues (2015) found no pattern of mood effects related to cultural fluency–disfluency, whether the event was one that entailed generally positive events (weddings, picnics) or generally negative ones (funerals, obituaries). Lin and colleagues (2018) replicated this pattern of null effects. However, lack of results using a particular self-reported measure does not rule out the possibility that cultural fluency yields some sort of affective response. The response may be the kind of low level or “primitive” affective response described by Gawronski and Bodenhausen (2007, 2011) as part of associative processing of propositions. Getting a measure of this kind of mood effect may require using either basic physiological measures or indirect measures such as liking or consumption (Winkielman, Berridge, & Wilbarger, 2005). Indeed, Zayas, Pandey, and Tabak (2017) found that Americans like Valentine’s Day-associated products (but not other products) more as Valentine’s Day nears. We interpret this increase in liking as implying that subtle carryover mood effects of cultural fluency may exist.

Inherence

Culture-as-situated-cognition theory predicts that people use the culturally rooted associative knowledge network that is on their minds (accessible) to make automatic predictions about what they observe. Mismatch between

implicit prediction and observation implies that the world is not as expected, that something is not right. This should undermine people's sense that the way things are now is the way things ought to be; hence, inherence and essentialism should be undermined. In contrast, a match between implicit prediction and observation implies that the world is as one expects it to be. This should bolster inherence and essentialism.

A number of studies have assessed change in belief in inherence as a function of change in cultural fluency and disfluency (Lin et al., in review-a; in review-b). In these studies, inherence is measured by asking people how much they agree or disagree with a series of statements that imply current practices are somehow natural, the way things "ought" to be rather than one of many possibilities (Salomon & Cimpian, 2014). The scale includes statements such as "It seems natural to use red in a traffic light to mean stop," "It seems ideal that toothpaste is typically flavored with mint," and "If intelligent organisms were discovered on another planet, they would probably communicate through sounds." Lin and colleagues (2018) divided participants in the United States, China, and Israel into two groups. In one group, participants saw culturally disfluent stimuli, and in the other, participants saw culturally fluent stimuli. For example, researchers showed Americans real Valentine's Day cards. Some were adorned with skull patterns, others with heart patterns. Israelis were shown photographs of real plated breakfasts. Some breakfast plates included cooked vegetables or meats; other breakfast plates included raw vegetables or eggs. Americans and Chinese were shown photographs of real weddings with brides in black or in white wedding dresses. In each case, the cultural products were from the country in which they were tested, yet they varied in their match (cultural fluency) or mismatch (cultural disfluency) with the typical, usual, traditional, and expected. In each case, participants exposed to the culturally fluent versus the culturally disfluent cue differed in how much they endorsed inherence. The feeling of fluency or disfluency "spilled over" to the subsequent task, and participants in the disfluent condition were more likely to disagree with statements such as "It seems natural to use red in a traffic light to mean stop," compared to participants exposed to the culturally fluent cue.

Well-Being

Culture-as-situated-cognition theory predicts that people use the culturally rooted associative knowledge network that is on their minds (accessible) to make automatic predictions about what they will observe. Repeated prediction error is likely to occur when people's values and goals differ from those of the culture in which they are embedded, when they move to a different culture, or when the culture in which they are embedded changes rapidly around them. For example, after immigration or migration, one's cultural expertise no longer applies to current contexts. By situating the ensuing experience within the cultural fluency and disfluency framework, it is easier to understand and experimentally test the psychological reaction to experiencing a new environment (also described as "culture shock"; Oberg, 1960). Culture provides meaning. In a new culture, making meaning can be tricky due to unfamiliar (Oberg, 1960, p. 177) and unpredictable (Adler, 1981) signs and signals; that lack of familiarity and predictability leads people to make erroneous predictions repeatedly.

In this section, we consider the possible downstream consequences for well-being and life satisfaction of repeated prediction error. Since people may interpret their repeated failures as implying something about their competence and perceived self-competence is associated with greater life satisfaction and well-being (Tafarodi & Swann, 1995), repeatedly making incorrect predictions may have downstream negative consequences for self-regard. Moreover, repeated experience of prediction error should undermine one's sense of competence and certainty that the world is a knowable, orderly place. This may undermine life satisfaction and well-being to the extent that this yields an implicit thought: "Things do not make sense to me, perhaps I am not competent. Perhaps I do not know myself as well as I think I do, either" (Smith, James, Varnum, & Oyserman, 2014; Skinner, 1996; Ward & Kennedy, 1992; Weisz & Stipek, 1982). Note that this line of reasoning implies that then simply being aware of a disjuncture between one's personal values and those of one's culture should not be sufficient to turn off the negative consequences of repeated prediction error. Negative consequences arise from repeatedly not being able to predict smoothly how situations will unfold.

While we did not find any studies testing these hypotheses directly, we found what we interpret to be supporting evidence in studies examining circumstances in which there is a likely disjuncture between predictions and observations. In these studies, people whose values differ from the average national norm experience lower well-being (Lun & Bond, 2013; Zou et al., 2009) and less satisfaction with their personal life (Fulmer et al., 2010) and social relationships (Friedman et al., 2010). Research finds the same result when there is a disjuncture with organizational values, goals, and beliefs (Elfenbein & O'Reilly, 2007). While these correlational results cannot address causation, we infer that research finds these associations because disjuncture leads to prediction errors, lower experienced self-competence and self-certainty. Indeed, people outside of their culture feel better after they receive reminders of their own culture (Fu, Morris, & Hong, 2015), presumably because when one is outside of one's culture, prediction errors are more likely, reducing experienced self-competence and self-certainty. The reminders of one's own culture bring back a more predictable world.

People whose values differ from their culture's values may or may not know that this is the case. People who know that their values differ from their culture's values have the extra task of trying to adjust for that, but they may not know how. Culture, after all, is not a set of explicit rules that can be systematically applied, but a gist sense of how "we" do things. Consider two everyday examples from American politics and university classrooms. Republicans and Democrats often experience people in the other party as being stupid or wrong or dangerous—and feel that the other party willfully misrepresents their own beliefs. The culturally fluent lens (that which seems to go without saying) is one's own; attempting to adjust to another lens is error-prone and awkward. Similarly, professors are often surprised by their poor course ratings and fail to understand how to properly adjust to improve student satisfaction. In both cases, being aware of a mismatch and even knowing quite a bit about the culture does not fully solve the problem. People who do not know that their values differ from their culture's values simply experience error without knowledge of why. Prediction errors occur because much of culture involves associative, rather than rule-based, propositional knowledge—a gut-based set of intuitions rather than a rule-based set of propositions for behavior (Gigerenzer & Gaissmaier, 2011). Gist-based processing outperforms rule-based processing when there are

too many variables for a set of rules to be applied or there are too many unknowns to know which rules to apply (see, e.g., Dijksterhuis, Bos, Nordgren, & Van Baaren, 2006). Hence, we predict that people who attempt to use rule-based processing to make predictions about how a culturally rooted situation will unfold are more likely to experience prediction errors than those using gist-based processing. Rule-based attempts that deplete experienced certainty, sense of well-being, and satisfaction are more likely when personal values mismatch those of one's culture, whether one is aware of this mismatch or not.

Doing

Culture-as-situated-cognition theory predicts that people will use accessible culturally rooted associative knowledge networks to make automatic predictions about what they will observe. Mismatch between implicit prediction and observation yields a metacognitive experience of difficulty, which implies that the world is not as expected, that something is not right. This sends a problem signal that requires systematic attention and reduces "going with the flow." How people interpret their metacognitive experience of difficulty matters; for example, difficulty might imply something about oneself or about the object under consideration, yielding different patterns of behavior.

Responses to Persuasion Attempts

Culture-as-situated-cognition theory makes a number of predictions about how people will respond to persuasion attempts by building on the elaboration-likelihood model (Petty & Cacioppo, 1986). First, superficial cues are more likely to be persuasive if the persuasive attempt occurs while people are experiencing cultural fluency. Second, what constitutes a high-quality argument should depend on the nodes central to activated culturally rooted associative knowledge networks. Third, accessible culturally rooted associative knowledge networks should focus attention on some cues and not others.

In culturally fluent situations in which observation seems to match implicit expectations, processing can remain shallow. Cultural disfluency, on the other hand, increases scrutiny of arguments and decreases reliance on peripheral cues. Since experienced cultural disfluency is a problem signal, disfluency should focus attention on argument quality. Culturally relevant cues require attention and care, so quality of persuasive argument matters; in contrast, culturally irrelevant cues can be ignored. The implication is that persuasive arguments using culturally irrelevant cues pass by unnoticed or are shallowly processed. Although focus on the interface between persuasion and cultural fluency and disfluency is just emerging, a number of studies support this line of reasoning, as we detail next.

Cultural Fluency Increases Persuasiveness of Superficial Cues

First, with regard to superficial cues and shallow processing, Mourey and colleagues (2015) randomly assigned participants to a culturally fluent or disfluent experience, then showed them a product and asked how much they were willing to pay for it. Shallow processing was all that was possible: The only information was a photograph and brief description, and the products on offer (a shovel, a phone charger keychain) were irrelevant to the specific culturally rooted associative knowledge network brought to mind by the prior task. Shallow processing seemed sufficient in the fluent, compared to the disfluent, conditions. Willingness to pay for a shovel was higher for people who had just seen photographs of a bride in white, a groom in black, and a tiered white wedding cake than for those who had just seen a bride in green, a groom in purple, and a tiered wedding cake decorated with colorful cogs. Willingness to pay for a phone charger keychain was higher for people who had just read sad obituaries compared to people who had just read happy obituaries. The consumption context in each of these studies implies approach (“Do you want this?”), so shallow processing yields approach behavior.

A cultural fluency perspective implies that people will “go with the flow” whether context implies approach (“Take this!”) or avoidance (“Do not take this!”). Support for this prediction that avoidance can be the culturally fluent thing to do comes from the studies of Yamagishi, Hashimoto, and colleagues (Hashimoto, Li, & Yamagishi, 2011; Yamagishi, Hashimoto, & Schug, 2008).

They demonstrated that a culturally fluent understanding of what a “go with the flow” response would be can lead to either approach or avoidance behaviors among both Americans and Asians.

Second, with regard to central cues and elaborated processing, experienced cultural disfluency, a problem signal, should focus attention on argument quality. We did not find studies testing this prediction directly. However, we found what we consider to be indirect evidence of the hypothesized effect. For example, in three studies, Briñol, Petty, and Wheeler (2006b) found that people experiencing a larger discrepancy between their implicit and explicit self-concepts were more sensitive to argument strength than were people experiencing smaller discrepancies. We interpret this result to mean that when the world is as expected (implicit and explicit self-concepts overlap), one does not need to process deeply. In contrast, error detection (implicit and explicit self-concepts differ) requires more elaborated processing. A direct test of this prediction is clearly needed to examine whether cultural disfluency triggers attention to argument quality as culture-as-situated cognition theory predicts.

Cultural Fluency Influences What Constitutes a High-Quality Argument

Culture-as-situated-cognition theory predicts that processing is situated. This means that what constitutes a high-quality argument (a central persuasion cue) depends on the activated culturally rooted associative knowledge network. A cue will be experienced as central if it is central to the activated culturally rooted knowledge network. The same cue will be experienced as peripheral if it is peripheral to the activated culturally rooted associative knowledge network. So, for example, a cue that might be central to an activated honor associative knowledge network might be peripheral to an activated individualistic associative knowledge network. A central cue should be required for persuasion to occur under conditions of cultural disfluency—then a high quality argument is needed; in contrast, under conditions of cultural fluency, a peripheral cue should be sufficient.

We did not find research testing this prediction directly. However, we did find illustrative research (Shavitt, Swan, Lowrey, & Wänke, 1994; Shavitt, Cho, & Barnes, [Chapter 25](#), this volume). Based on this research, we predict

that an accessible culturally rooted associative knowledge network influences whether a persuasion cue is experienced as peripheral or central. Consider what might happen if an honor versus an individualistic knowledge network was accessible. If an “honor” knowledge network is accessible, then persuasive cues linked to target image (e.g., endorser attractiveness, reputation) may be a central persuasion cue, in part because one’s image in the eyes of others is part of an honor associative knowledge network. If so, then when an honor associative knowledge network is accessible, cultural disfluency should increase the persuasive quality of endorser attractiveness and reputation. At the same time, persuasive cues that are not central to an honor associative knowledge network should not be processed centrally, but rather processed shallowly if at all. Similarly, if an “individualistic” knowledge network is accessible, then persuasive cues linked to one’s own sensory experience may be a central persuasion cue, in part because one’s own internal experiences are a more central part of an individualistic associative knowledge network. If so, then when an individualistic knowledge network is accessible, cultural disfluency should increase the persuasive quality of sensory experience.

Cultural Fluency Focuses Attention on Some Cues and Not Others

Finally, culture-as-situated cognition theory predicts that accessible culturally rooted associative knowledge networks focus attention on some cues and not others. Culturally relevant cues require attention and care; hence, the quality of persuasive argument matters. Culturally irrelevant cues are either unnoticed or are noticed but processed shallowly. In order for people to be motivated to centrally process an argument in the first place, the topic must feel relevant to them. Which culturally rooted associative knowledge networks are accessible in the moment should affect what is experienced as relevant. Once a cue is experienced as relevant, it will be processed and may or may not yield the intended persuasive effect.

First, consider what a collectivistic knowledge network includes. In addition to content, it includes procedures and goals related to finding and maintaining connections and relationships (Masuda, Russell, Li, & Lee, [Chapter 8](#); Nisbett, [Chapter 7](#), this volume; Oyserman, et al., 2009). This means that once activated, people will be sensitive to connection and

relationship cues. Indeed, in a series of studies, Mourey, Oyserman, and Yoon (2013) showed that when researchers activate a collectivistic knowledge network, people process even unrelated products as if they were sets: They are willing to pay more to keep a set even if the set was constructed on the spot; they notice more connections among objects; they are unwilling to keep part of a “broken” set, even if the set was just constructed.

In one study, Mourey and colleagues (2013) offered participants a snack and a drink, and after participants had chosen one of each, they learned they could only have one (a snack or a drink) not both. In another study, participants chose two puppies for a friend who wanted two, only to learn that the lease only allowed for one, not two. In a third study, participants made choices of cellphone chargers, cases, and earbuds, only to learn that some of their choices were not available. In each of these studies, participants were asked how they would like to proceed. Participants in the condition in which a collectivistic knowledge network was activated were more likely to act as if their chosen items formed a unit. In contrast, participants in the condition in which an individualistic knowledge network was activated were more likely to act as if they had made a number of separate item choices. For example, in the snack and drink study, participants described their choice as a set, reporting things such as “I chose Coke and a cookie, both begin with the letter C!” If they could not have their full set, they preferred to go back to the original list and choose something else—and as a result, they ended up with a snack or a drink that was neither their initial top choice snack nor their initial top drink. In contrast, if researchers activated an individualistic knowledge network, participants were more likely to act as if they had chosen the best snack from the snack list and the best drink from the drink list as two separate choices. Hence, if they could not have both, these participants were more likely to take one of their top choices (the top drink or top snack) rather than go back to the list to choose a snack or drink that had not been their top choice. This same pattern applied to puppies and cell phone accessories.

Kwon, Saluja, and Adaval (2015) took this insight that a collectivistic knowledge network includes a connecting “set-making” mental procedure into the domain of persuasion. When Kwon and colleagues activated a collectivistic knowledge network, participants cared about the fit between

elements of a persuasion attempt (e.g., the photos and text from an ad). In this case, participants acted as if the elements of a persuasion attempt were supposed to be a set, so they used the fit between elements as a persuasion cue. In contrast, when Kwon and colleagues activated an individualistic knowledge network, participants did not seem to process elements of the persuasion attempt using a “set-making” mental procedure. Just as in the snack studies (Mourey et al., 2013), participants in Kwon and colleagues’ (2015) individualistic mindset condition processed each cue separately.

Though none of these studies directly tested cultural fluency and disfluency, we operationalize the culturally fluent response in these studies as using the procedure in the activated cultural mindset—it felt right. A set-making procedure was activated in the collectivistic mindset condition, so people used it. The snack-and-drink task did not necessarily require this procedure, but people in the collectivistic mindset condition used this culturally fluent procedure even though it resulted in forgoing top choices for lesser ones once the top choices were considered as if they formulated a set. The Kwon and colleagues (2015) studies allowed for a more direct test of the implications of cultural fluency for persuasion. People in the collectivistic mindset condition used the set-making procedure and tried to process an ad’s photo and text as a set. When photo and text did not fit well together, people were less persuaded; and when they did fit together well, people were more persuaded. A set-making procedure was not on the minds of people in the individualistic mindset condition; hence, whether the photo and text fit well together had no bearing on persuasion.

Mindful and Mindless Action

Culture-as-situated-cognition theory makes a number of predictions about how cultural fluency and disfluency influence the likelihood of engaging in mindless and mindful action. First, people will be more likely to go with the flow—approach when contexts cue approach and avoid when contexts cue avoidance—under conditions of cultural fluency. Second, this effect should be limited to situations in which experienced fluency (ease) and disfluency (difficulty) are interpreted as being about the context itself rather than as being about the self. As we described in the section on well-being, if

experienced fluency and disfluency are taken to imply something about the self, then cultural disfluency is depleting, yielding a sense of “Perhaps I am not competent.”

Cultural Fluency and Disfluency and Contextual Cues of Approach or Avoidance

Cultural fluency is likely to increase the chance that people will “go with the flow.” Depending on whether the context cues approach or avoidance, going with the flow may either mean “keep going” or “stop.” Although studies that show this effect with avoidance situations have not yet been conducted, this is what we find in situations that cue approach. Mourey, Lam and Oyserman (2015) set up conditions of cultural fluency and disfluency in a series of experiments involving approach situations (picnics, buffets) with American picnickers and Hong Kong Chinese buffet-goers. Participants interpreted their metacognitive experiences of ease or difficulty as informative of whether to keep going. Participants randomly assigned to receive a culturally fluent plate loaded more food onto their plates than those randomly assigned to receive a neutral plate. Participants randomly assigned to receive a culturally disfluent loaded less food on their plates than those randomly assigned to receive a neutral plate.

For example, during a Fourth of July picnic, picnickers who received stars-and-stripes decorated plates loaded on average 25% more food (in weight) on their plates than picnickers who received plain white plates. During a Labor Day picnic, picnickers who received bats-and-pumpkins decorated plates loaded on average 18% less food (in weight) on their plates than picnickers who received plain white plates. During Chinese New Year, buffet-goers who received red-bordered plates loaded on average 18% more food (in portion size) on their plates than buffet-goers who received black-bordered plates. They also loaded larger portions on their plates than buffet-goers who received red- or black-bordered plates after Chinese New Year—24–29% more. After Chinese New Year, the color of plate border was no longer a fluency signal. Across studies, when plate decorations were culturally fluent, the metacognitive experience of ease triggered “going with the flow”—loading up plates in an *approach* (vs. *avoid*) setting in which eating is expected. Cultural fluency emerged from the match between plate

and immediate context (the holiday that was happening) and was not a fixed feature of the plate itself.

Cultural Fluency and Disfluency and the Self

We next consider situations in which cultural fluency and disfluency are experienced as having implications for the self. Culture-as-situated-cognition theory predicts that people will infer from prediction error that something about the situation requires attention unless they have reason to infer that prediction error is due to their own deficiencies. If they infer that prediction error is due to their own deficiencies, they should experience a reduced sense of efficacy and competence.

We did not find research directly testing this prediction, but we did find indirect support in a series of experiments by Koo, Shavitt, Lalwani, Dai, and Chinchanchokchai (2011a, 2011b). Evidence is indirect, because Koo and colleagues did not activate a culturally rooted associative knowledge network. They randomly assigned European American and Asian participants to use either an attentional style associated with collectivism (pay attention to background) or an attentional style associated with individualism (focus on pieces). Using a culture-as-situated-cognition lens yields the hypothesis that the culturally fluent procedure will be the one that is on the mind. A procedure can be on the mind because it is associated with a momentarily cued cultural mindset or because it is associated with a chronically accessible cultural mindset. People will use the accessible procedure even if another one might better serve them, unless they are explicitly directed to use a different one. In these cases, a mismatch between implicit prediction (“The mental procedure on my mind is the right one to use!”) and the unfolding situation (“I was told to use a different mental procedure!”) can occur. Mismatches are experienced as disfluency (difficulty). The consequence of a mismatch depends on situational cues as to whether the source of disfluency stems from one’s self or from one’s environment. The experimental context Koo and colleagues created led participants to interpret it as being about themselves. After completing the task, participants were asked to focus on themselves. Participants rated themselves as having less self-control if they were randomized to conditions in which prediction error was likely—being asked to use a mental procedure

without an a priori cue that it would be requested. Interpretation of what prediction error implied for the self mattered: Participants in the prediction error conditions ate more of the offered snacks, evaluated a tempting chocolate bar more positively than a healthy multigrain bar, and preferred a familiar, easy choice to an unfamiliar one that would require more thinking. This was true for Asians asked to use the “focus on pieces” attentional style (associated with individualism) and for European Americans asked to use the “pay attention to background” attentional style (associated with collectivism). Though not tested, presumably, higher subsequent self-control would be found for participants primed with individualism and given the “focus on pieces” instruction and for participants primed with collectivism and given the “pay attention to background” instructions.

UNDERSTANDING PROCESS: ARE VIOLATIONS CULTURALLY FLUENT OR CULTURALLY DISFLUENT?

Relevant Associative Networks Must Exist

Whether a given cue is likely to generate a prediction error depends on whether a relevant culturally rooted associative knowledge network exists (is available in memory) and on whether it is activated (accessible in working memory). If a culturally rooted associative knowledge network doesn't exist in memory, then it cannot generate predictions or an experience of cultural fluency or disfluency. For example, Mourey and colleagues (2015) had small-town Midwestern European American participants choose foods from a Chinese buffet. Unbeknownst to participants, they were randomly assigned to plate color, and the amount of food they chose was being measured. Half received a white plate with a red border. The other half received a white plate with a black border. The study took place during Chinese New Year. Plate border did not affect experienced cultural fluency among these small-town Midwestern American participants for whom the culturally rooted associative knowledge network connecting “Chinese New Year” and “red” did not exist. When asked, they reported not knowing when

Chinese New Year is or anything about how to celebrate it. In this study, the relevant knowledge network was simply not available for use.

Cues Interact Probabilistically with Situations

Even if a culturally rooted associative knowledge network is available (exists in memory), a particular cue may or may not activate it. Whether or not a particular culturally rooted associative knowledge network is activated depends on the centrality of a cue to the network and features of the immediate situation. Some cues are more central to a culturally rooted associative knowledge network than other cues, and some situations call attention to a culturally rooted associative knowledge network. Central cues and attention-calling situations should have more robust effects than peripheral cues and subtle situations.

[Figure 20.4](#) depicts a peripheral (top panel) and a central (bottom panel) Valentine's Day cue manipulation. The top left panel is from Mourey and colleagues (2015), who used a medium pink border (vs. a black border, top right) on the questionnaire. Lin and colleagues (2018) manipulated cultural fluency of Valentine's Day using a central cue: Valentine's Day cards. The figures have been reproduced in black and white, so a verbal description of what participants saw is needed to understand the manipulation. The cards were adorned either with hearts (fluent, bottom left) or skulls (disfluent, bottom right). Examples from their study are shown in the bottom panel of [Figure 20.4](#). The fluent hearts were red or medium pink (the same color as used in the fluent border). The disfluent Valentine's card also had heart shapes and loving statements, but included skulls. Instead of pink and red, the disfluent Valentine's day care was black and creamy white. Even in the disfluent cases, the cards were unambiguously for Valentine's Day, just with an unexpected feature. As predicted, the Valentine's Day skulls-patterned cards created a robust experience of disfluency—it was found both during Valentine's Day and a month later (Lin et al., 2018).

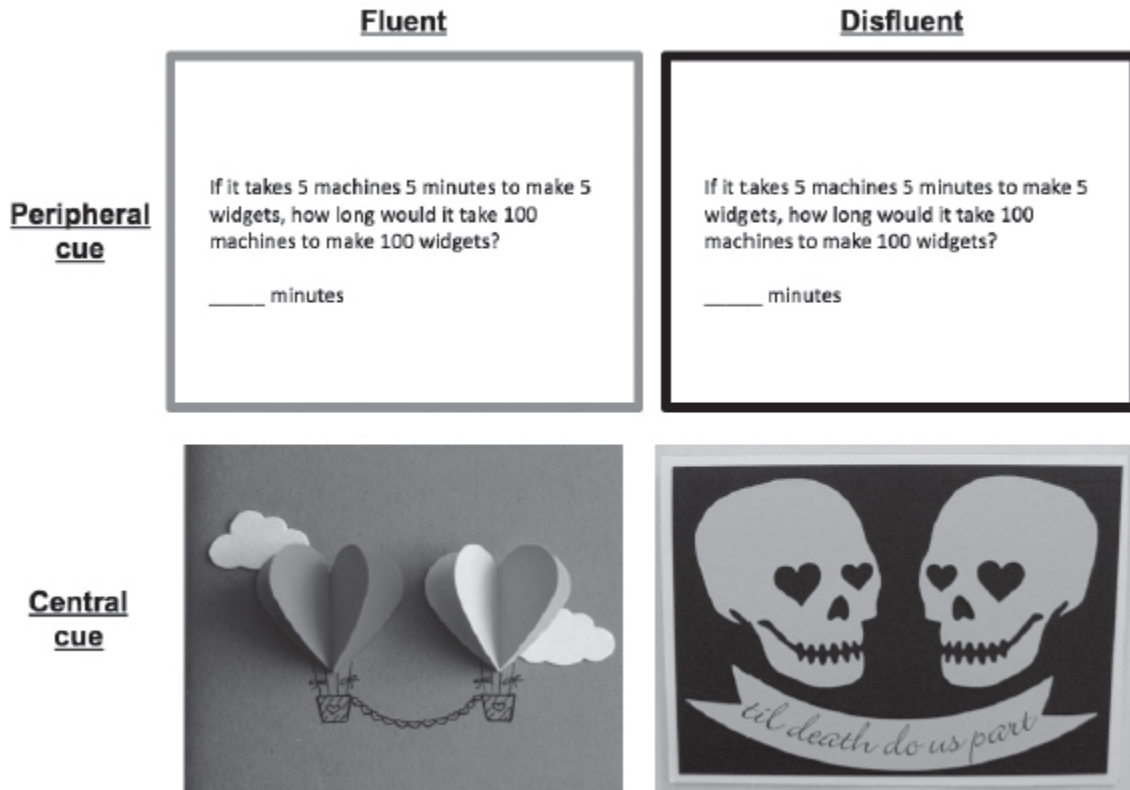

FIGURE 20.4. Examples of Valentine’s Day fluency manipulations used by Mourey et al. (2015; top row: manipulation of a relatively peripheral cue) and Lin et al. (under review-a; bottom row: manipulation of a more central cue). On the left are images displaying the relatively culturally fluent conditions, and on the right are images displaying the relatively culturally disfluent conditions. For the manipulation illustrated in the top row (the pink vs. the black border), the pink border (top left, here in gray) yielded an experience of cultural fluency only when the experiment was conducted on Valentine’s Day; for the manipulation illustrated in the bottom row (the hearts vs. the skull patterns), the skulls yielded an experience of cultural disfluency whether or not the experiment was conducted on Valentine’s Day. Color version is provided at <http://doi.org/cmn9>. The balloon hearts image is used courtesy of Adoration by Michelle Chow, adorationdesign.com. The skulls image is used courtesy of Rachele Rouquié, Black Lamb BK, Brooklyn, New York.

In contrast, peripheral cues require situational support to become relevant. For example, the color of the border on a printed questionnaire is presumably a peripheral cue. However, a peripheral cue may trigger feelings of cultural fluency or disfluency when the associative knowledge network is activated. For example, on Valentine’s Day, a pink-bordered questionnaire might be experienced as particularly fluent, whereas a black-bordered questionnaire would not be; but when it is not Valentine’s Day, pink and black are just colors. To test this prediction, Mourey and colleagues (2015)

asked participants to complete a Cognitive Reflective Task (CRT, Frederick, 2005). Half of participants were asked on Valentine's Day and half were asked a week later. At each point in time, half of participants received the CRT with a pink border surrounding the questions and half with a black border or no border at all. On Valentine's Day, the pink presumably felt fluent; indeed, participants in the pink-border condition were less likely to apply rules in solving the problems compared to participants in the black-bordered or no-border condition. A week after Valentine's Day, pink was just a color, no more or less fluent than black or no border. Indeed, participants in all conditions were just as likely to apply rules in solving problems as participants in the disfluent conditions on Valentine's Day. Similarly, the cultural fluency effects that Mourey and colleagues showed among Chinese participants using red-bordered plates during Chinese New Year disappeared after Chinese New Year.

Multiple Associative Knowledge Networks Could Be Cued

People have available to them many culturally rooted associative knowledge networks. Features of the situations influence which of these available networks is on the mind. Imagine looking at a series of wedding photographs. In one's own culture, the event "a wedding" would likely be perceptually salient, activating a "wedding" culturally rooted associative knowledge network. In the United States, the activated network generates an automatic prediction: "The bride will wear a white gown." If observation matches prediction, people likely experience cultural fluency. If observation mismatches prediction ("The bridal gown is not white!"), people likely experience cultural disfluency. Indeed, white is a plausible, automatic prediction in China as well. Wedding photographs depicting a bride in white yielded cultural fluency, while a bride in unexpected color gowns—green or black—yielded cultural disfluency in both the United States and China (Lin et al., 2018; Mourey et al., 2015). Outside of one's culture, cues are less likely to be read as transmitted, so not only are prediction errors more likely, but also mismatch of prediction to observation is less likely to be experienced as cultural disfluency. For example, Americans may fail to recognize that the

photograph in Figure 20.5 on the right is of a Muslim Indian wedding since their “wedding” culturally rooted associative knowledge network is less likely to be activated. Failing to predict that this is a wedding yields an error signal if informed that it is a wedding, but not otherwise. Learning that an error occurred reduces certainty in one’s ability to predict what is a wedding outside one’s culture but is unlikely to undermine certainty in one’s ability to predict within one’s culture.

FIGURE 20.5. Left: Jewish couple holding a themed wedding (image from <http://urbanbridesmag.co.il>). Right: A Muslim Indian wedding (image used with permission from the bride and groom). These images may activate alternative associative knowledge networks (e.g., Victorian themes on the left, love on the right), since other cues are dominant. Color version is provided at <http://doi.org/cmn9>.

Even within one’s own culture, “wedding” is not the only associative knowledge network that might be cued. If other unique features are perceptually more salient, other associative knowledge networks are likely to be activated. In these cases, the color of the bridal gown may no longer feature in prediction. For example, for Jews, in addition to the colors of the bride and groom’s attire, a Jewish wedding implies icons of Jewish tradition (standing under a *chuppah* canopy, a *kippah* cap on the groom’s head). Consider the left half of Figure 20.5. The wedding depicted is part of a Jewish Israeli wedding in Israel, yet it includes so many unique features that the activated knowledge networks may be about other things. Activated

networks may include “Victorian” or “themed parties” or “new experiences” or “times I have traveled” or “people I know from different places.” Hence, whereas, on the surface, this wedding might appear to be culturally disfluent, if the interpretive lens is not “wedding,” then mismatch to prediction may not occur; hence, neither will it evoke cultural disfluency or its downstream consequences. The same is true for the photograph on the right side of [Figure 20.5](#). For those who are aware of the cultural frame, the Muslim Indian couple here are clearly in the midst of their wedding ceremony activities; others may simply see vibrantly colored clothing and a happy couple and never realize that the context is a wedding.

Prediction Error Is Culturally Disfluent Violation of Expectation: Rule Breaking May Be Predicted

While cultural disfluency studies have focused on prediction error, prediction error is not the same as rule breaking. Culturally rooted associative knowledge networks should yield predictions about when norms, practices, and rules are likely to be violated. People expect thieves to steal, addicts to consume the object of their addiction, and suspicious characters to cheat. If the predicted rule breaking is subsequently observed, people should experience cultural fluency and their subsequent confidence in their predictions should increase. Culturally rooted associative knowledge networks include relevant knowledge of what the rules are, what rule breaking means, when rules are likely to be broken, and who is likely to break rules. Two studies reported in Oyserman (2012) provide evidence for this prediction. In one study, participants were Hong Kong Chinese and the broken rule involved eating on the Hong Kong metro system, a finable offense. In the other study, participants were Mormons and the broken rule involved experiencing addictive dependence, breaking a tenet of Mormonism to avoid addiction to any substance that could alter the health or strength of one’s body or mind. In the metro system study, Hong Kong Chinese participants were asked to imagine a fellow metro rider looking around furtively and then either pulling out a lunch (and eating) or pulling out a book (and reading). In the addictive dependence study, Mormon participants were asked to imagine a fellow Mormon addicted to buttery

croissants and unable to go a single morning without eating one or two or simply enjoying those buttery croissants everyday. In both cases, the setup of the situation led to a clear prediction of rule breaking. Reading that a rule was broken yielded cultural fluency and hence no shift to systematic reasoning as documented by use of associative reasoning on a CRT task. In contrast, cultural disfluency ensued for the Hong Kong participants who expected a rule to be broken (because the MTR rider seemed not to want to be noticed), but then observed a situation in which it was not broken (the MTR rider pulled out a book to read, rather than food to eat). That cultural disfluency was cued was inferred by the shift to systematic reasoning in this condition as documented by use of systematic reasoning on the CRT.

SUMMARY

Culture-as-situated-cognition theory predicts that people have available, but not necessarily simultaneously accessible, a large number of culturally rooted associative knowledge networks. People use their accessible culturally rooted associative knowledge networks to make automatic, implicit (not necessarily conscious) predictions about how situations will unfold. Because people are expert in their own cultures, what unfolds is typically experienced as a match with prediction, yielding a metacognitive experience of ease. Experienced ease does not have to be interpreted, but it often is, and what it implies depends on whether the situation, the self, or something else is the momentary focus of attention. Depending on focus, experienced ease might mean that the situation is safe and requires no further attention, that the world is as it should be, that one is competent and knows how the world works, that one can just go with the flow, or that the choice one is about to make is the correct one.

Even in one's own culture observation sometimes mismatches implicit or explicit prediction. This mismatch yields a metacognitive experience of difficulty. Experienced difficulty does not have to be interpreted, but it often is, and what it implies depends on whether the situation, the self, or something else is the momentary focus of attention. Depending on focus, experienced difficulty might mean that the situation is risky or dangerous and requires further attention, or that the world may not be as it should be.

Otherwise, experienced difficulty might mean that one is not particularly competent and does not really know how the world works, that one has to consider which rules apply, or that the choice one is about to make may not be the correct one. How people interpret their metacognitive experience of difficulty matters; difficulty might imply something about oneself, the action itself, or about the situation.

Hence, *whether* ease or difficulty is experienced and *how* experienced ease or difficulty is (explicitly or implicitly) interpreted both matter. Whether ease or difficulty is experienced depends in part on which associative knowledge network is cued and the context in which it is cued. Because of spreading activation in associative knowledge networks, effects are probabilistic rather than certain. While experienced ease does not require action, experienced difficulty does. We predict that, over time, an accumulation of experienced ease or difficulty matters. Chronically experiencing cultural fluency (ease) should increase self-certainty and well-being. Chronically experiencing cultural disfluency (difficulty) on the other hand, should undermine both self-certainty and well-being.

We summarized evidence of downstream consequences of cultural fluency and disfluency for thinking, feeling, and doing. With regard to thinking, we addressed two literatures, the existing literature on cultural mindsets and the emerging literature on cultural (dis)fluency. The cultural mindset literature shows that people use the mental procedures that are part of accessible, culturally rooted associative knowledge networks to solve problems at hand. This can help or hinder performance depending on whether the accessible mental procedure (e.g., analytic, holistic) matches or mismatches the task at hand. We interpreted these well-documented effects in light of cultural fluency and disfluency: Using the activated mental procedure feels fluent and hence is applied whether it helps or hinders performance. The exception is situations in which task instructions call for a particular procedure; then the procedure itself will be used whether or not it feels fluent and how people interpret their experienced difficulty will depend on what their attention is drawn to—themselves or the situation. We then considered how experiences of cultural fluency and disfluency should influence information processing generally. We predicted that cultural fluency is the default experience and provides a “no problem” signal,

preserving gist-based associative reasoning as the default reasoning style whether or not that style is the best match to the task at hand.

We predicted that cultural disfluency provides a “problem here” signal, which should turn on systematic reasoning. Whether the default associative “go with your gut” or systematic “use a rule” is the better reasoning style to use depends on features of the task. Hence, culture-as-situated-cognition theory predicts that whether performance improves or is undermined by cultural fluency and disfluency depends on the match between task demands and cued reasoning style. Performance is not a main effect of cultural fluency or of cultural disfluency.

With regard to feeling, we found no evidence of an explicit immediate affective response to culturally fluent or disfluent experiences, but we did find some indirect effects through product ratings and some effects on feelings of inherence. Compared to cultural fluency, cultural disfluency reduces experienced inherence (the feeling that all is right with the world). We also found indirect evidence for effects of chronic cultural disfluency on well-being, life satisfaction, and self-regard; ongoing gaps between expectation and observation undermine well-being, life satisfaction, and self-certainty. Further research is needed to better understand the role of feelings in cultural fluency; this research might productively examine implicit and other indirect measures.

Finally, with regard to taking action, culture-as-situated-cognition theory predicts that the effect of persuasion attempts and contextual cues on behavior depends on activated culturally rooted associative knowledge networks and on how people interpret the experienced ease or difficulty resulting from a match or mismatch between automatic implicit prediction and observation. Indeed, the activated culturally rooted associative knowledge network influences which features of persuasion attempts capture people’s attention. A match or mismatch between observation and culturally rooted implicit prediction influences whether people pay attention to argument quality. Whether experienced cultural fluency and disfluency result in more or less mindful behavior depends on whether experienced ease and difficulty are interpreted as being about features of the situation or features of oneself.

A cultural fluency and disfluency perspective sheds light on how culture functions as a meaning-making system. Each culture is unique, and cultural

expertise involves a large set of culturally rooted associative knowledge networks that include a richly detailed set of goals and mental procedures. These networks include but are not limited to “individualistic,” “collectivistic,” or “honor” mindsets. As social beings, people are sensitive to situational cues; even minor contextual cues can activate different culturally rooted associative knowledge networks. People are influenced by how they (implicitly or explicitly) interpret the match and mismatch between what accessible culturally rooted associative knowledge networks lead them to implicitly expect and how situations unfold. Effects require that a knowledge network be accessible at the moment of judgment, not merely available in memory, and effects may occur even when people do not endorse accessible norms, beliefs, practices, or goals. By demonstrating these effects, we solve a puzzle that arises from between-group comparison models of culture that focus on differences in cultural mindsets or identities. The puzzle is that while these differences exist, small situational cues are often sufficient to change seemingly deeply rooted patterns of behavior in ways that are not predicted by a between-group difference approach.

ACKNOWLEDGMENTS

This chapter was much improved by comments from faculty and students across an array of institutions, including, most recently, the Open University of Israel, the University of California, Irvine, and Southwest University, Chongqing China, and members of the culture and self lab at the University of Southern California.

NOTES

1. A number of theories, including the New Look (Bruner, 1957; Bruner & Goodman, 1947), confirmation bias (Wason, 1960), self-fulfilling prophecy (Merton, 1948; Snyder, 1984), and stereotype theories (Hamilton & Trolier, 1986), would predict that expectations usually appear to be met because people see what they are ready to see. Yet in spite of people’s readiness to perceive what they expect to perceive, expectations are sometimes violated. What happens next? A culture-as-situated-cognition approach makes novel predictions about the predicted downstream consequences of expectation violations, as well as expectation confirmations, by introducing the concepts of cultural fluency and cultural disfluency.

2. A parallel productive line of research does not focus on cultural mindsets but on cultural, bicultural, and multicultural *identities* (e.g., Morris et al., 2015; Leung & Koh, [Chapter 21](#), this volume). These identities can be thought of as culturally rooted associative knowledge networks with

centrally located identity nodes. To test causal process, cultural researchers interested in cultural identities randomly assign participants to experience visual (e.g., images of Chinese cultural icons) or semantic (e.g., describing ways in which one is different from one's friends) stimuli meant to cue culturally rooted associative knowledge networks including identity as central nodes (e.g., Oyserman & Sorensen, 2009). Research documents individual differences in how these knowledge networks are integrated as cultural identities (e.g., Cheng, Lee, & Benet-Martínez, 2006; Huynh, Nguyen, & Benet-Martínez, 2011).

CHAPTER 21

Psychological Science of Multiculturalism

Angela K.-y. Leung and Brandon Koh

Multiculturalism is a multifaceted phenomenon. We begin this chapter by discussing broadly the ideological foundations of multiculturalism and the theoretical perspectives underlying the formation of multicultural identity. The core of the chapter reviews the psychological ramifications of multiculturalism, including cultural frame switching, acculturation and adjustment outcomes, promotion of creativity, and bilingualism's benefits for executive control functioning and creativity. We end the chapter with a discussion of recent research on cosmopolitanism and the theoretical and empirical utility of bridging the study of cosmopolitanism to understanding global issues such as environmental sustainability.

The previous decade has seen research advances in studying the phenomenon of multiculturalism in its many forms. The ideology of multiculturalism celebrates not only the harmonious presence of diverse cultural groups but also the respect and recognition toward maintaining the integrity of different cultures. During the 2015 National Day Rally Speech, the Prime Minister of Singapore, Lee Hsien Loong, eloquently addressed how multiculturalism in part transformed Singapore from a third-world country 50 years ago to a first-world metropolis today: “We separated from Malaysia because we believed in this ideal of a multi-racial society. . . . We encouraged all the communities to come together and yet gave each community space to maintain their own cultures and their own ways of life.

When delicate and awkward issues arose, we dealt with them together.” Multiculturalism—exemplified by the happy coexistence of different cultures’ ways of living while maintaining a sense of unity—may be viewed as not only as a national strength but also an individual asset. Our main goal in this chapter is to review and integrate research related to multiculturalism in order to put into perspective what being a multicultural society and a multicultural individual entails in situations of cultural mixing and cultural integration.

In this chapter, we first define multiculturalism at the individual, collective, and national levels, followed by a discussion of multiculturalism in relation to universalism and polyculturalism, to further illuminate its meanings to individuals and the larger society. Second, we identify some models for bicultural/multicultural identity in recent literatures. We then provide in the core of the chapter a review of the psychological implications of multiculturalism on cultural frame switching, acculturation success, and creativity. Next, we provide a brief review of the psychological implications of bilingualism (or multilingualism) on cognitive functioning, including executive control and creative benefits. Finally, we discuss cosmopolitanism as an emerging individual orientation for multicultural people and share some insights of how systematic investigations of cosmopolitan orientation can contribute to the study of timely global issues such as environmental sustainability.

There are two things to note. First, we use the terms “biculturalism,” “multiculturalism,” “bilingualism,” and “multilingualism” throughout the chapter rather loosely, depending on whether we refer to two or more cultures or languages. Second, although we mainly associate multiculturalism with a pluralistic cultural orientation toward ethnocultural groups, many principles we discuss (e.g., multicultural identity, acculturation, cultural frame switching) are not only defined by the nation-state, but can be “cultural” groups defined by one’s profession (e.g., Cheng, Sanchez-Burks, & Lee, 2008), religion (Verkuyten & Yildiz, 2007), gender (e.g., Hedges & Nowell, 1995), and sexuality (e.g., Fingerhut, Peplau, & Ghavami, 2005). Multiculturalism clearly has transformative implications that go beyond recognizing the diversity of ethnic cultures.

WHAT DOES MULTICULTURALISM ENTAIL?

Multiculturalism is an all-encompassing concept, with a broad scope that can describe an individual, a collective, or a nation-state. First, on the individual level, a person is considered multicultural if he or she is continuously exposed to, immersed in, and attached to more than one culture in various degrees (Benet-Martínez & Haritatos, 2005; Berry, 2003; Padilla, 2006; Markus & Hamedani, [Chapter 1](#), this volume). Benet-Martínez (2010, p. 626) provided a rather comprehensive definition of who is considered a multicultural person: “those who are mixed-race and mixed-ethnic, those who have lived in more than one country (such as expatriates, international students, immigrants, refugees, and sojourners), those reared with at least one other culture in addition to the dominant mainstream culture (such as children of immigrants or colonized people), and those in intercultural relationships may all be considered multicultural (Berry, 2003; Padilla, 2006).” Notably, an important distinction may be made between a multicultural person who possesses multicultural knowledge and a multicultural person who endorses a multicultural identity. Extensive exposure to a multicultural environment is conducive to acquiring knowledge about diverse cultures, but it does not necessarily entail a sense of identification, attachment, or loyalty to those cultures (Benet-Martínez, 2010; Benet-Martínez & Haritatos, 2005; Haritatos & Benet-Martínez, 2002; Hong, Wan, No, & Chiu, 2007). The relation between multicultural knowledge and multicultural identity is likely to be asymmetrical; people tend to be knowledgeable about the cultures with which they identify but may not identify with the cultures about which they are knowledgeable (Leung & Cohen, 2011).

Second, on the collective level, a group of people interacts to form a multicultural group or team. Multiculturalism at the level of the social group concerns whether individuals’ day-to-day social transactions involve others who are culturally or ethnically diverse (Brett & Moran, 2011). This multicultural experience becomes inevitable given increased global mobility and the fast disappearance of provincial and homogenized communities (Crisp & Turner, 2011).

Third, on the national level, the notion of multiculturalism is ascribed with a greater variety of meanings. It can be referred to as a demographic

fact of the nation-state (i.e., the composition of ethnic groups in the population), an ideology (i.e., the general orientation toward cultural pluralism and intercultural inclusion), and a public policy orientation (Berry, Kalin, & Taylor, 1977). For policies to embody the ideology of multiculturalism, Berry and Sam (2013) emphasized two important values for the state to endorse—the maintenance of heritage cultures and identities (cultural diversity), and the full and equitable participation of all ethnocultural groups in the larger society (social equity and inclusion). To uphold multiculturalism and intercultural inclusion, the state could consider formulation and implementation of policies that support, for example, multiple official languages, minority media outlets, dual citizenship, and the public holidays, religious practices, and dress codes of cultural minorities (Benet-Martínez, 2010). Accordingly, multiculturalism should not be misconceived as the tolerated presence of many independent cultural communities or subcultures in a society, as such an orientation is actually considered a form of segregation if cultural diversity is not accompanied by intercultural inclusion and equitable participation (Berry & Sam, 2013). As Berry and Sam further argued, this misconception seems to account for why some European societies such as Germany and the Netherlands have recently asserted that multiculturalism has failed.

We can further clarify the notion of multiculturalism by seeing it in perspective of other, interrelated or contrary ideologies. In a recent review, Morris, Chiu, and Liu (2015) discussed multiculturalism, universalism, and polyculturalism as three valuable political frameworks that serve different goals within culturally diverse liberal societies. Universalism presupposes uniformity of human nature and believes ethnic, racial, and cultural boundaries are superficial. Whereas its accompanying color-blind policies establish impartial standards to dismantle discrimination and expand civil rights for minorities, the one dominant standard is often that of the dominant group (Morris et al., 2015). The emphasis on disregarding cultural differences might also suffocate opportunities for cultural learning and perspective switching. In contrast, multiculturalism is the ideology that embraces cultural preservation, equal group status, and collective action. However, multiculturalism is associated with the tendencies of affirming and holding on to cultural authenticity and eschewing judgments of other cultures, which might sometimes widen the distance between cultural

groups, fuel intercultural misunderstanding, and even increase the use of cultural stereotypes (Gutiérrez & Unzueta, 2010; Wolsko, Park, Judd, & Wittenbrink, 2000). These rather undesirable outcomes might help explain the common misconception that multiculturalism supports the coexistence of multiple cultural groups but fails to realize intercultural inclusion and equitable participation (see Berry & Sam, 2013). Polyculturalism is based on the premises of cultural pluralism and interaction, in that cultural influence on people is partial and plural, with individuals serving as conduits for facilitating intercultural interactions. The emphasis is not on cultural maintenance or reproduction, but on cultural hybridity that often catalyzes cultural change and renewal (Prashad, 2001). Polycultural people are more receptive to criticisms of their own cultural tradition (Rosenthal, Levy, & Moss, 2012), seeking intergroup dialogue (Rosenthal & Levy, 2012), and espousing a malleable (vs. essential) view of culture (Chao, Chen, Roisman, & Hong, 2007; Tadmor, Chao, Hong, & Polzer, 2013; see also No et al., 2008). Nevertheless, polyculturalism might fall short of the functions served by universalism in protecting civil equality and by multiculturalism in fostering solidarity within cultural communities (Morris et al., 2015). Thus, it is advisable not to make a case that one ideology is superior to the other on all dimensions.

MODELS OF BICULTURAL/MULTICULTURAL IDENTITY

Simply put, identity pertains to one's self-concept that is related to group membership (Hamers & Blanc, 2000; Noels, Pon, & Clément, 1996), so bicultural/multicultural identity is the part of the self-concept that has to do with cultural affiliation (Nguyen, Huynh, & Benet-Martínez, 2009). Individuals who adhere to a multicultural identity often label themselves as belonging to two or more cultural groups (e.g., a Chinese American; Benet-Martínez, 2010). Individuals' degree of multicultural identification varies, with those showing higher identification being more likely to behave in accordance with cultural norms appropriate to the setting (Jetten, Postmes, & McAuliffe, 2002; Terry, Hogg, & White, 1999), to respond more effectively to cultural cues (Hong, Morris, Chiu, & Benet-Martínez, 2000), to shift their

cultural orientations appropriately (Mok & Morris, 2009), to be more interculturally competent (van Oudenhoven & Benet-Martínez, 2015), and to be less constrained by cultural groupthink (Mok & Morris, 2010).

Perspectives of Multicultural Identity

“Cultural adaptation” is a process by which individuals are immersed in continuous contact with another culture, with the development of multicultural identity as an outcome of the process (Berry, 2003). LaFromboise, Coleman, and Gerton (1993) typologized individuals who identify with two or more cultures as alternating or fused biculturals. “Alternating biculturals” oscillate between two cultures based on situational demands, whereas “fused biculturals” integrate the two cultures to form an emergent, distinct cultural identity.

Moving away from a typological perspective, Benet-Martínez, Leu, Lee, and Morris (2002) developed the construct of bicultural identity integration (BII), which captures biculturals’ perceived compatibility of their two cultural identities on two independent continuums. The “cultural distance dimension” is a cognitive component concerning the extent to which the two cultural identities are perceived as blended and overlapping (vs. dissociated and nonoverlapping). The “cultural conflict dimension” is an affective component capturing the extent to which the two cultures are felt to be harmonious and compatible (vs. conflicting and incompatible). BII is mainly derived from people’s subjective perception of the two cultures’ congruence, but not the objective differences between those cultures (Benet-Martínez, 2010).

From the social-cognitive perspective, acculturation can be understood as cognitive reorganization of one’s cultural identity. This perspective theorizes that individuals’ cultural identity might progress sequentially from alternation to integration. For example, Amiot, de la Sablonniere, Terry, and Smith (2007) proposed a four-stage model to include processes of anticipatory categorization, categorization, compartmentalization, and integration. The first two stages deal with highly differentiated social identities analogous to low levels of BII or identification with only one of the two affiliated cultures. Compartmentalization holds multiple identities to

remain separate, so that individuals behave like alternating biculturals whose identification with the two cultures is context-dependent and experienced conflict is dampened. Finally, integration is a stage in which individuals simultaneously identify with multiple cultures and resolve conflicting feelings more completely (Amiot et al., 2007). Similarly, in Gocłowska and Crisp's (2014) three-stage model, to resolve inconsistencies of multiple social identities, individuals *alternate* their identities across contexts, *integrate* unrelated elements of their identities, and finally *broaden* their self-definition. Such a broadened and inclusive sense of self facilitates accessibility and integration of concepts, thus benefiting creativity.

Together, most theories adopting a typological perspective on multicultural identity largely converge on the view that multicultural people manage their identities through alternation or integration, with some of them putting a more nuanced focus on alternation (Amiot et al., 2007; Birman, 1994) and some on integration (Gocłowska & Crisp, 2014). Another perspective treats bicultural identity as a continuum of identity integration (e.g., BII). Some researchers also see integration as a more advanced stage of multicultural identity than alternation (Amiot et al., 2007; Gocłowska & Crisp, 2014), which aids in resolving dissonant feelings induced by multiple cultural identities through the development of a broadened self-concept (Berry, 2003; Berry, Phinney, Sam, & Vedder, 2006).

Despite recognition that an integrated identity confers much advantage, scant research delves into why and how integration actually occurs. According to Gocłowska and Crisp (2014), alternation allows individuals to navigate their social worlds effectively only if the two worlds can be kept separate. When individuals face situations in which two or more cultures collide at the same time and in the same space (i.e., culture mixing; see Chen et al., 2016), they face the challenges of resolving intraindividual conflicts and maintaining belongingness to multiple cultures, which threatens a cohesive self-identity (Amiot et al., 2007; Walsh, Shulman, Feldman, & Maurer, 2005). In such cases, biculturals engage in integration to find a "middle" ground to blend both of their identities. For instance, Indian transnational youth in Canada adopt a fusion of ethnic Indian and Western clothing style to exhibit their blended cultural identity (Somerville, 2008).

As for "how," integration often entails recategorizing multiple cultural identities into one unified, higher-order conceptual category (Gocłowska &

Crisp, 2014). For instance, a mother might integrate her seemingly nonoverlapping identity of being an engineer by broadening her self-definition to be a “professional woman.” In so doing, her sense of self-concept would readily associate with a wider base of cognitions, without the need to switch between the two identities’ meaning systems (Amiot et al., 2007; Gocłowska & Crisp, 2014). If the to-be-combined categories are seemingly incongruent (e.g., “Harvard-educated” and “carpenter”), one might generate *emergent* attributes not inherently present in the original categories so as to coherently forge an integration of the conflicting identities (e.g., thinking of a Harvard-educated carpenter as highly skilled yet nonmaterialistic; Amiot et al., 2007).

Multiracial Identity

Multiracial identity theory extends multicultural identity theories to provide an insight into how multiracials or individuals of mixed-race develop their identity. Like culture, race is conceived of as a socially constructed category in common parlance (Sanchez, Shih, & Wilton, 2014). For example, a light-skinned African may be identified as black in the United States, but as white in Argentina. Additionally, race is not biologically an “essential” or natural category. There is more genetic variation within than between races (Goodman, 2000; Graves, 2001; Hirschfeld, 1996; Marks, 1995; Tooby & Cosmides, 1990; Zack, 1995).

Research indicates that multiracial individuals seek to develop an autonomous and integrated identity like multiculturals (Cheng & Lee, 2009; Sanchez et al., 2014). Whereas multicultural individuals may voluntarily choose not to participate in multicultural environments, it is difficult for multiracials to ignore their mixed racial heritage. Multiracial individuals face more challenges when they choose not to identify with either of their racial categories (Gaskins, 1999; Sanchez et al., 2014), when they struggle to justify their identity choices to themselves and also to society, and when they lack role models to look up to (Shih & Sanchez, 2005). Furthermore, multiracials are often perceived as minorities (Ho, Sidanius, Levin, & Banaji, 2011) and marginalized by both the dominant and minority communities (Shih & Sanchez, 2005). Forming an integrated multiracial identity thus

becomes a paramount challenge for multiracials to overcome in order to achieve healthy adjustment (Shih & Sanchez, 2005). In an in-depth review, Sanchez and colleagues (2014) proposed the identity autonomy perspective to understand the fundamentals of multiracial identity development. They identify three levels for the construction of racial identity: (1) self-definition (how one views his or her own race), (2) other definition (how others view an individual racially), and (3) contextual identification (how racial identity is shaped by context; also see Rockquemore, Brusma, & Delgado, 2009). Accordingly, identity denial and inconsistency occur when self-identity is inconsistent with others' views. Under these circumstances, a sense of individual autonomy—that is, a sense of free choice and authentic expression of the self (Deci & Ryan, 1995)—is crucial for healthy identity development (Sanchez et al., 2014), well-being (Sanchez, Shih, & Garcia, 2009), and resistance to stereotype threats and discrimination (Jackson, Yoo, Guevarra, & Harrington, 2012; Shih, Bonam, Sanchez, & Peck, 2007). However, some multiracial individuals may not perceive their identity choice as autonomous. For instance, when multiracials are forced to choose from one racial or cultural category in census surveys (“Are you Asian or American?”; Gaskins, 1999) or when they seek affirmative action (Good, Chavez, & Sanchez, 2010), they can be pressured into facing an identity dilemma and experience identity denial (Sanchez et al., 2014).

Overall, findings on multiracials' adjustment outcomes are mixed and dependent on specific domains of adjustment in question (Shih & Sanchez, 2005). Negative adjustment outcomes can be buffered by adhering to the incremental belief that race is a social construct and is largely malleable (Shih et al., 2007). An integration of multiracial identities also leads individuals to greater pride for their multiracial background (Cheng & Lee, 2009). In contrast, when individuals do not hold a highly integrated multiracial identity or face identity denial, they might contrastively react against the salient racial cue in order to prove their loyalty with the nonsalient racial group or to manipulate others' perceptions (Cheryan & Monin, 2005; Sanchez et al., 2014). These reactions are analogous to those experienced by low-BII individuals when situations provoke them to defend their nonsalient cultural identity and they therefore exhibit behaviors that contrast the situation's salient cultural cue (Mok & Morris, 2013). Furthermore, for less integrated multiracial individuals, identity shifting

tends to be a reaction to outside pressures and the need to earn approval; such shifted racial self-definition is likely to be perceived as a less autonomous choice and is associated with depression and negative attitudes about being multiracial (Sanchez et al., 2009, 2014).

Bilingual Identity versus Bicultural Identity

Although interrelated, feeling bilingual and feeling bicultural as part of the self-concept are quite distinct notions (Fielding & Harbon, 2013; Moran, 2001). As Kanno (2003) described these intertwined identities: “By bilingual and bicultural identity I mean where bilingual individuals position themselves between two languages and two (or more) cultures, and how they incorporate these languages and cultures into their sense of who they are” (p. 3). To define oneself as a bilingual, one has to *connect* to more than one language through communicating with and learning from members who speak the language (Duff, 2007, 2015), to *interact* in both of the languages competently (Fielding & Harbon, 2013), and to *invest* one’s motivation in language learning and to make good use of the language-learning opportunities (Norton, 2000). In a study on Australian students who took part in a bilingual French–English program, Fielding and Harbon (2013) showed that participants’ development of a bilingual identity hinged on their perceived ability to engage in competent and ongoing interaction in both languages (i.e., balanced bilingualism). However, most students in the study defined themselves as a bicultural, regardless of their self-perceived bilingual skills.

It is relevant to ask whether immigrants’ adherence to a bilingual identity will support an assimilation hypothesis (i.e., increase identification with the host culture and reduce identification with the home culture) or an integration hypothesis (i.e., increase identification with both host and home cultures). Research tends to support the integration prediction (Berry et al., 2006; Sam & Berry, 2006). Among minority Francophones from Saskatchewan, those who show confidence in English (their second language) also tend to show confidence in French (their native language), and their bilingual proficiency enhances both their French and English identities. Thus, proficiency in a second language has helped them feel

dually affiliated with both communities (Gaudet & Clément, 2009). Similarly, another study showed that bilingualism facilitates an integrative response to maintain dual cultural identities among minority Francophones outside of Quebec and minority Anglophones in Quebec (Freynet & Clément, 2015).

There is also evidence that the timing of acquiring the two languages is associated with how the two corresponding cultures are cognitively organized and understood. Among Mexican American students who self-identified as an English–Spanish bilingual, compound bilinguals who learned the languages simultaneously tended to view the two cultures as overlapped and blended (e.g., Chicano as an emergent third culture), whereas coordinate bilinguals who learned the languages in different settings tended to view the cultures as distinct and compartmentalized (Nguyen & Ahmadpanah, 2014; see also Ervin & Osgood, 1954). These findings point to how simultaneous language learning is related to the ways the two cultures are mentally and experientially organized.

MULTICULTURAL EXPERIENCE AND ITS PSYCHOLOGICAL IMPLICATIONS

Cultural Frame Switching

Individuals who adhere to mainly one cultural identity or have not acquired much knowledge of other cultures tend readily to act upon their habitual ways of thinking or behaving. Given that multicultural individuals have multiple possible ways to categorize themselves, their cognitive and behavioral reactions are often context-specific, depending on which identity the situation activates and deems applicable (Gocłowska & Crisp, 2014). This process, widely known as “cultural frame switching,” depicts how bicultural or multicultural individuals flexibly oscillate between cultural frames in order to act congruently with the meaning systems and behavioral rules salient in the situational press (Hong et al., 2000). For instance, bicultural Chinese Americans primed with American cues made more dispositional attributions, whereas those primed with Chinese cues made more situational attributions (Hong et al., 2000). With language being one

means to cue a culture, administering a study in English or Spanish aligned individuals' behaviors with the norms representative of the respective cultures (Ramírez-Esparza, Gosling, Benet-Martínez, Potter, & Pennebaker, 2006). Bicultural individuals could exhibit inferences based on evoked cultural cues; in one study, Hong Kong Chinese biculturals switched their moral inferences corresponding to cues from American or Chinese culture spontaneously, even within the same experimental session (Fu, Chiu, Morris, & Young, 2007). Researchers also have observed the cultural frame-switching effect on self-concept and values (Ross, Xun, & Wilson, 2002) and behavioral decisions in economic games (Wong & Hong, 2005). Relatedly, it was argued that bilingual individuals (who are often biculturals) are better at cultural frame switching (Gołowska & Crisp, 2014), because they exercise better executive control in processing conflicting information and switching between rules or changing demands (Bialystok & Viswanathan, 2009). However, as immersion in language and immersion in culture probably occur simultaneously in this and similar research, we cannot clearly attribute causality for bilinguals' improved cultural frame switching to their language.

Interestingly, bicultural individuals might not always frame-switch in a way that responds congruently with the activated cultural cues. Benet-Martínez and colleagues (2002) showed that whereas high-BII individuals who perceive their two cultures as blended and nonconflicting displayed assimilative responses to align their attributional judgments with the salient cultural primes, low-BII individuals who perceive the cultures as dissociated and conflicting displayed contrastive reactions against the primes. Similar assimilative and contrastive patterns were found with self-perceived personality (Mok & Morris, 2009), conformity of judgments (Mok & Morris, 2010), and evaluative forecasts of others' behavior (Mok & Morris, 2011). Further inquiries revealed that high-BII individuals tended to assimilate after exposure to positive cultural cues, but they tended to contrast after exposure to negative cultural cues (Cheng, Lee, & Benet-Martínez, 2006). This suggests that high-BII individuals adaptively switch to maintain a positive self-identity and strategically distance themselves from negative cues that are discordant with a positive self-view (Cheng et al., 2006). As for low-BII individuals, their cultural reactance might serve to "call out" their noncued cultural identity, thus protecting them from the threat of losing

this identity that is often dissociated from the one made salient in the situation (Mok & Morris, 2013).

Acculturation and Adjustment Success

Individual-Level and Collective-Level Acculturation

Acculturation is commonly understood as a bi-dimensional process, because individuals do not necessarily become more distant from their culture of origin when they make contact with new cultures (Sam & Berry, 2006; Yoon et al., 2013). Many multicultural individuals are inevitably immigrants, ethnic minorities, or indigenous people (Berry, Kim, Minde, & Mok, 1987), who face the acculturation challenge of deciding to what extent they (1) are to culturally socialize into and participate in the mainstream culture and (2) maintain their culture of origin and ethnic identity (Berry, 1980, 2001, 2003). Their negotiation of these two acculturation dimensions results in a typology of four distinct acculturation strategies (Berry, 2003). “Assimilation” is the strategy to seek contact with the mainstream culture, while giving up the native cultural identity. In contrast, “separation” is the strategy to hold onto the native cultural identity but avoid interactions with the mainstream culture. People adopt the integration or biculturalism strategy when they participate in the new culture while retaining their ethnic identity. The marginalization strategy is adopted if people show little interest in getting involved with both the dominant and ethnic cultures.

Parallel to these individual acculturation strategies, Berry (1980, 2009) posited that the dominant groups on the collective level have their preferred acculturation ideology: melting pot (parallel to assimilation), segregation (parallel to separation), multiculturalism (parallel to integration), and exclusion (parallel to marginalization). These orientations manifest through national policies and public attitudes that exert an expectation from the dominant group on how immigrants should acculturate to the host culture (see also Mesquita, De Leersnyder, & Jasini, [Chapter 19](#), this volume). Obviously, the integration strategy is most likely to take root in societies where the dominant group favors the multicultural ideology, thus supporting an inclusive attitude toward cultural diversity and perceiving

dual cultural identities to be compatible and nonthreatening to social cohesion (Berry & Kalin, 1995; Berry et al., 2006; Duncan, 2005; Garcea, 2003).

While substantial empirical support was found for the four distinct acculturation profiles (e.g., Berry et al., 2006; Ryder, Alden, & Paulhus, 2000), other indicates some problems (for critiques of this approach, see Rudmin, 2003; Rudmin & Ahmadzadeh, 2001). For example, Montreuil and Bourhis (2001) have found a highly positive correlation between immigrants' assimilation and separation scores ($r = .60$), which are supposed to be antithetical to each other. Relatedly, van de Vijver, Helms-Lorenz, and Feltzer (1999) showed that the acculturation scale is arguably unidimensional, with integration at one end of the dimension and assimilation, separation, and marginalization at the other end. Despite these empirical challenges, the use of the fourfold acculturation models remains widespread in the literature.

Berry (2008) has discussed how globalization could initiate different strategies for acculturation. First, the hegemonic dominance of globalization may lead to homogenization of world cultures and their people, so that nondominant cultures disappear under dominant ones (i.e., assimilation). Second, both the dominant and nondominant cultures may undergo mutual change, so each of them retain its dominant features and share other common qualities (i.e., integration). Third, people may strive to reject the dominant culture or further engage in some sort of revitalization movements in order to reverse the process of global cultural domination and to reaffirm their cultural heritage through localization (i.e., separation). Fourth, globalization might destroy nondominant cultures altogether, but their members choose not to identify with the dominant cultural nexus (i.e., marginalization). Interestingly, in a study of immigrant youth from 26 different cultural backgrounds, living in 13 cultures, a majority of them endorsed maintenance of their heritage culture by preferring integration or separation as opposed to assimilation or marginalization (Berry et al., 2006). Thus, the facile generalization that globalization equals homogenization might not stand given the trend that younger generations across the globe are more rejecting of the melting pot ideology (Berry, 2008).

Individually, acculturating individuals experience changes in their attitudes, cultural identity, and behavioral repertoires; collectively, they

experience changes in social structures, institutions, and shared cultural practices (Berry, 2005). According to Berry, it is meaningful to keep acculturation at the individual level (psychological acculturation) and at the collective level (cultural acculturation) distinct. Notably, individuals are active agents responding to the cultural context within which acculturation occurs; there are vast individual differences observed in how people participate in and derive their goals from the acculturation arena.

When the changes accompanied by psychological acculturation are relatively straightforward behavioral shifts, such as learning the language of the dominant culture and getting accustomed to new cultural practices, acculturation outcomes are termed “adjustment” (C. Ward, Bochner, & Furnham, 2001). Adjustment that evolves into longer-term stable changes further reflects success at “adaptation,” which can be further distinguished between psychological adaptation (increased psychological and physical well-being) and sociocultural adaptation (maneuvering competently in intercultural contexts; C. Ward, 1996). When the changes concern more intense or problematic cultural conflicts, such as overcoming discrimination from the dominant group, acculturation outcomes give rise to acculturative stress (C. Ward et al., 2001).

We identified two emerging topics in the acculturation literature. One important research endeavor concerns the positive link between individuals’ acculturation strategy and their adjustment and adaptation success. While integrationism is recognized as the most ideal strategy, researchers have started to acknowledge some potential benefits of marginalization. Another line of research focuses on the interactive acculturation process between immigrants and the local or dominant group. It is conceivable that members of the dominant culture also experience acculturation when newcomers enter their territory, and research has examined this phenomenon in the form of enculturation and cultural encroachment.

The Acculturation–Adjustment/Adaptation Link

Acculturation can be both a stressful and a growth-enhancing process. Some researchers have shown that immigrants experience distress, depression, social isolation, and a less coherent sense of self when acculturating into a

new culture (Jang & Chiriboga, 2010; Juang & Cookston, 2009; Walsh et al., 2005; Weisman et al., 2005), while others have suggested that acculturation provides opportunities for stress-related growth by promoting greater mental strength, less culturally bound worldviews, a sense of perseverance, and more satisfying interpersonal relationships (J. Kim & Kim, 2013; J. Kim, Suh, & Heo, 2012; Moores & Popadiuk, 2011). For instance, immigrant emerging adults from the former Soviet Union in Israel showed higher levels of autonomy and relatedness with their parents than did nonimmigrant emerging adults (Walsh et al., 2005). In a recent study, J. Kim, Malonebeach, Heo, Kim, and Kim (2015) found that Korean immigrants in the United States who had more difficulty acculturating into the American cultural value system reported higher levels of personal growth.

Among the four strategies, marginalization is often identified as associated with the highest level of acculturative stress, and integration the least. For example, marginalizers tend to show more dysfunctional and deviant behaviors such as delinquency, dropping out of school, and substance abuse (Berry, 1997, 2003; Berry & Kim, 1988; Del Pilar & Udasco, 2004), and integrationists tend to gain more benefits in different life domains (Berry, 1997; Phinney, Horenczyk, Liebkind, & Vedder, 2001). In a study on Irish immigrants, those who pursued the integration strategy showed the least health problems, particularly in comparison to their counterparts adopting marginalization (Curran, 2003). In terms of discrimination (which has a strong negative impact on both psychological and sociocultural adaptation; Berry et al., 2006), youth who were integrated reported experiencing the least amount of discrimination, followed by assimilated and separated youth. As expected, those who were marginalized experienced the most discrimination. In terms of more direct effects on psychological and sociocultural adaptation, second-generation immigrant youth settled in Canada or France reported higher adaptation scores (representing more positive psychological well-being and better adjustment in school and in the community) if they adopted integration, but lower scores if they adopted marginalization (Berry & Sabatier, 2010). Those adopting assimilation or separation generally fall in between. These findings on immigrant youth are consistent with research on adults (e.g., Berry, 1997; Berry & Sam, 1997).

Arguably, high-BII individuals tend to acculturate better to the second culture than do low-BII individuals. BII was found to positively associate with adjustment, as reflected in higher self-esteem, greater life satisfaction and psychological well-being, and lower depression and anxiety (for differential effects between BII blendedness and BII harmony, see Benet-Martínez et al., 2010; Chen, Benet-Martínez, & Harris Bond, 2008; Downie, Koestner, ElGeledi, & Cree, 2004; Downie, Mageau, Koestner, & Liodden, 2006).

Nevertheless, contradictory findings exist. Some research is supportive of the positive link among integrationism, adjustment, and adaptation (e.g., Berry, 1994, 1997; Sam, Vedder, Liebkind, Neto, & Virta, 2008; Szapocznik & Kurtines, 1980; C. Ward & Kennedy, 1994), yet other research did not obtain the same positive link or even found a negative one (Burnam, Hough, Karno, Escobar, & Telles, 1987; Rotheram-Borus, 1990). In an attempt to summarize the relationship between acculturation strategies and adaptation success, Nguyen and Benet-Martínez (2013) conducted a meta-analysis across 83 studies that involved more than 23,000 participants. Their analysis generally confirmed the integration–adaptation relationship, but the relationship’s magnitude was qualified by the type of methods used to measure acculturation strategies. Specifically, the relationship varied between $r = .02$ and $r = .11$, depending on whether the research assessed acculturation with direct measures (i.e., measuring each of the acculturation strategies with its separate subscale), unidimensional scales (i.e., equating identification with one culture to relinquishment of another culture), and bidimensional scales (i.e., capturing involvement with two cultures using two independent subscales), respectively. Another recent meta-analysis by Yoon and colleagues (2013) revealed that integration strategy through both external acculturation (e.g., language and behavioral adaptations) and internal acculturation (e.g., identification with the new culture) produced the most favorable results for mental health, followed by assimilation and separation; marginalization had the least favorable relationship to mental health. It is believed that individuals adopting integrationism have more enriched and flexible psychological and behavioral repertoires to competently deal with different psychological (e.g., depression, anxiety, uncertainty) and sociocultural challenges (e.g., intercultural conflicts and miscommunication) resulting from participating in two cultures (Benet-

Martínez, Lee, & Leu, 2006; Tadmor & Tetlock, 2006; Yoon, Langrehr, & Ong, 2011).

Although research is generally in support of the acculturation–adaptation link, more recently researchers have started to attend to the neglected group, marginalizers, who do not identify with either their own ethnic culture or the host culture. As noted by Rudmin (2003), the relationship between marginalization and dysfunction is dependent on whether dysfunction is operationalized as stress and marginalization as difficulty in life (vs. simply low identification with both the ethnic and host cultures). As an alternative, some researchers have chosen to see marginalization in terms of constructs such as “cultural independence” or “cosmopolitanism,” in order to move away from its pejorative connotation (e.g., Cannon & Yaprak, 2002; Gillespie, McBride, & Riddle, 2010; Glaser, 1958; Razzouk & Masters, 1986; Rudmin & Ahmadzadeh, 2001; see also our discussion of cosmopolitan orientation in this chapter). The critical distinction between these constructs is reflected in how marginalization, cultural independence, and cosmopolitanism are measured. While marginalization is essentially measured by whether individuals respond negatively to seeing the value of maintaining their native cultural identity and of developing relationships with people in the host culture, questions that presumably reflect an orientation toward cultural independence or cosmopolitanism are often phrased in a more positive light (e.g., “seeing oneself as a citizen of the world”; see Pichler (2011)). We suppose it is highly worthwhile to pursue research to understand in what ways (psychologically and behaviorally) marginalizers, cultural independents, and cosmopolitans are similar or different from each other, as well as the adaptation outcomes of these groups. For example, it is plausible that marginalizers are people who feel at home nowhere, and cultural independents are those who feel at home anywhere. It is also plausible that cosmopolitans display a higher moral and prosocial obligation to humanity at large than the marginalizers and cultural independents do (see “[Cosmopolitanism in the Multicultural World](#)”). Research is needed to test these speculations.

It has been theorized that cultural independence and cosmopolitanism promote efficacy, because a lack of strong identification with either culture might allow individuals to transcend any cultural limitations and to develop secure self-identities (Gillespie et al., 2010; Nash & Schaw, 1962). Evidence

has supported the hypothesis that cultural independents or cosmopolitans are more likely to have better sociocultural adaptation to a second culture (Kosic, 2002), to show above average school performance (Saruk & Gulutsan, 1970), to excel at work as successful professionals (U. Kim, 1988), to develop autonomous personal worldviews and higher creative potential (Cannon & Yaprak, 2002), to exhibit more complex thinking and better discriminatory capability to select the best aspects of different cultures for improving performance (Tadmor, Tetlock, & Peng, 2009), and to display highly sought after qualities such as rationality, objectivity, logical thinking, and effective management skills (Mol, 1963). One study showed that Mexican managers who pursued integration or cultural independence were more likely to occupy upper management positions and be promoted within their organizations than others who identified strongly with either the Mexican culture or the new American culture brought by American employees working in their companies (Gillespie et al., 2010).

Similar to the construct of “cultural independence,” the interactive acculturation model (IAM) developed by Bourhis, Moise, Perreault, and Senecal (1997) proposed individualism as an orientation in which people “define themselves and others based on their personal characteristics rather than on their group membership” (Bourhis, Barrette, El-Geledi, & Schmidt, 2009, p. 444). Whereas marginalists find it problematic to identify with either the dominant or the native culture, individualists are not concerned with maintaining their native cultural identity or participating in the dominant culture. Of import, individualists are distinct from the marginalists given their tendencies to emphasize personal qualities and goals, to downplay group ascriptions, and to interact with other immigrants and members of the dominant group in a nondifferentiating manner. It was found that undergraduate students (consisting of local European American and African American students and immigrant Asian and Hispanic students) attending a Los Angeles multicultural university showed more harmonious intercultural relations if they endorsed integrationism or individualism, but more problematic and conflicting relations if they endorsed the other three acculturation orientations (Bourhis et al., 2009).

Acculturation as a Mutual Process

Dominated by the study of how non-dominant groups acculturate, the acculturation literature has paid relatively less attention to the acculturation process experienced by members of the dominant group who strive to either safeguard or open up their culture in response to increased cultural diversity (Berry, 2005). This attests to the reciprocity or mutuality of acculturation that involves both the non-dominant and dominant groups (Berry, 1997; Bourhis et al., 1997; Kalin & Berry, 1996). The dominant groups hold certain expectations toward immigration policies, cultural diversity, or the preferred acculturation strategy of immigrants (Berry & Kalin, 1995; Mesquita et al., [Chapter 19](#), this volume). Societies that are supportive of a positive multicultural ideology favor immigrants adopting the integration strategy and seek to provide both hardware (e.g., health care, school curricula) and software support (e.g., cultivating social norms about cultural openness, opportunities for intergroup contacts) that are conducive to sustaining cultural pluralism.

To demonstrate the interaction between the dominant group's acculturation orientation toward immigrants and immigrants' adjustment outcomes, Berry and Sabatier (2010) compared the discrimination experience of second-generation immigrant youth in Montreal and Paris, where immigration policies are clearly different. Canada is identified as having successfully endorsed the multicultural ideology that encourages cultural maintenance and equal participation in the mainstream population and one's own minority group (Berry, 2003; Berry & Kalin, 1995). Since the passing of a national policy of multiculturalism in 1971, Canada received a large amount of immigrants, and the country is highly culturally diverse (Noels & Berry, 2006). France, on the other hand, tends to support "assimilationist citizenship" that encourages immigrants to adapt to the local ways of life (Sabatier & Boutry, 2006). Their levels of cultural diversity and immigration were considered moderate. Berry and Sabatier (2010) found that immigrant youth in Montreal who pursued the integration strategy experienced less discrimination and better cultural adaptation, but those who followed the marginalization path fared the poorest. In contrast, keeping contact with one's heritage culture served as a basis for discrimination for the immigrant youth who settled in Paris; they experienced the highest discrimination if they pursued separation or

integration, but experienced the least amount of discrimination if they pursued assimilation or marginalization.

Other research also examined how the local population's acculturation expectations toward immigrants led to different intergroup dynamics (González, Sirlopú, & Kessler, 2010; Piontkowski, Florack, Hoelker, & Obdrzalek, 2000). For example, within the bilingual city of Montreal, the Anglophone host has a longer history of integrating immigrants and encouraging demographic vitality in their community than the Francophone host (McAndrew & Proulx, 2000), and student immigrants were found to feel more welcomed and to show more integration within the Anglophone community than they did within the Francophone community (Montreuil & Bourhis, 2004). Results showed that Anglophones expected immigrants to be more integrationist and individualist than did Francophones. However, among those who expected immigrants to pursue integrationism or individualism, both Anglophones and Francophones had more harmonious intergroup relationships with these newcomers (see also Brown & Zagefka, 2011; Pfafferott & Brown, 2006; Zagefka & Brown, 2002). This is in line with the finding that endorsement of the multicultural ideology in the larger society led to a lowered sense of threat among the dominant group, which in turn encouraged more positive attitudes toward immigrants (C. Ward & Masgoret, 2006).

In a recent study, Ramelli, Florack, Kusic, and Rohmann (2013) showed that immigrants' perceived communication effectiveness and friendship with members of the receiving culture at the time of arrival fostered their contacts with the host culture 7 years later, particularly for those with higher need for cognitive closure. This is consonant with anxiety/uncertainty management theory (Gudykunst, 1998), as perceived effectiveness in managing anxiety/uncertainty when interacting with unfamiliar others can promote further seeking of contact.

To further show that acculturation is a mutual process, researchers have studied how mainstream cultural members adjust to the presence of immigrants or sojourners. For example, "cultural encroachment" is the process in which the dominant group is influenced by a second culture, and these changes take place in the dominant group's own territory (Gillespie et al., 2010). An example is that managers in Hong Kong adhered to values similar to those of the managers in the United States, suggesting that they

may have experienced value shifts after working extensively with American managers who came to work in the Hong Kong office (Ralston, Gustafson, Cheung, & Terpstra, 1993). A similar result was found among Indonesian managers as their orientations on individualism and power distance had become more similar to American managers after having worked extensively with them (Heuer, Cummings, & Hutabarat, 1999).

Findings from the acculturation literature hold important policy implications for securing social capital in the local community. Social capital, defined as “social networks and the associated norms of reciprocity and trustworthiness” (Putnam, 2007, p. 137), is a valuable resource for promoting individuals’ health and employment (Berkman, 1995; Lin, 1999; Putnam, 2000; Seeman, 1996), lowering crime rates (Sampson, Raudenbush, & Earls, 1997), and increasing societal functioning (Putnam, 2000). Social capital can benefit community members even if they have not directly participated in the social networks (e.g., Sampson, 2001). In the context of diversity, Putnam (2000) makes a further distinction between bonding and bridging social capital. “Bonding social capital” involves ties between individuals who are similar in some important ways (e.g., ethnicity) and serves to mobilize solidarity within communities. In contrast, “bridging social capital” involves ties between different ethnicities and can generate information exchange or foster business connections, thus benefiting innovation and economic progress (Putnam, 2000, 2007).

Arguably, increased diversity could blur ingroup–outgroup categories to foster bridging social capital. However, empirical works have more often suggested that diversity increases outgroup distinction and facilitates ethnocentrism. Drawing from the census data, Putnam (2007) found that American people tend to “hunker down” as immigration and ethnic diversity increase within the community, which is accompanied by observable reductions in trust, altruism, cooperation, and building of friendship both within and between ethnic groups. Of import, Putnam clarifies that diversity does not actually increase intergroup conflict or hostility; rather, people withdraw from their collective life and “hunker down,” which is analogous to a turtle hiding in its shell. This calls for research to study how nations can go beyond showing mere tolerance with ethnic coexistence to foster integration and build shared identities, so as to accumulate both bonding and bridging social capital (Putnam, 2007).

Further research might also examine how a nation's acculturation model helps attenuate the “hunker down” effect of increased immigration and diversity, which also informs public policy formulation.

Promotion of Creativity

We only briefly cover the ramifications of multiculturalism on creativity here, as another chapter in this volume reviews this topic (see Chiu & Hong, [Chapter 26](#), this volume).

Multicultural exposures have drastically increased opportunities for intercultural learning and for the synthesis of local and foreign ideas (Leung & Chiu, 2008, 2010; Leung, Maddux, Galinsky, & Chiu, 2008; Maddux & Galinsky, 2009), thus fostering a creative process that brings into being something both novel and useful (Amabile, 1996; De Dreu, Baas, & Nijstad, 2008). Evidence for the creative benefit of multiculturalism from both historiometric and psychometric research abounds. In his aggregate-level historiometric investigations, Simonton (2008) analyzed creative activity in a given nation or civilization over historical time. The pattern is rather clear that countries tended to experience creativity booms after periods in which they (1) underwent nationalistic revolts and rebellions (e.g., the Golden Age of Greece appeared after the revolt against the Persian Empire and Greek civilization was fragmented into different city-states; Simonton, 1975), (2) opened their civilization to foreign immigrants (e.g., Chinese Buddhist monks, Korean artists, and Christian missionaries entered the Japanese territory; Simonton, 1997, 2000), or (3) had their citizens travel or study on foreign soils. The inflows of foreign influences afford the emergence of polyglot civilizations that are overtly multicultural and at the same time support prominent creative activities. In individual-level historiometric investigations, analyses of over 300 eminent 20th-century personalities (Goertzel, Goertzel, & Goertzel, 1978), Nobel laureates (Moulin, 1955), and U.S. scientists (Levin & Stephan, 1999) revealed that most creative geniuses have been either foreign born, lived overseas, or studied abroad. These historiometric inquiries provide correlational support for cultural heterogeneity fueling creativity.

Other research has approached this proposition from either a multicultural knowledge or a multicultural identity perspective. From the multicultural knowledge perspective, the effect of increased multicultural contacts on creativity is consonant with a basic tenet of the creative cognition approach, which theorizes that the acquisition of different knowledge systems is a precursor to the generation of creative ideas (Finke, Ward, & Smith, 1992; T. Ward, Smith, & Vaid, 1997). Bringing together disparate ideas from different cultural sources, multicultural individuals have a broader knowledge base at their disposal to experiment with in their creative pursuits (Cheng et al., 2008; Leung et al., 2008). Considering disparate conceptions also offers multicultural individuals the opportunity to exercise their creative muscles as they destabilize their structured and routinized mindsets and appreciate seemingly incompatible perspectives (Maddux & Galinsky, 2009). Multicultural navigators are prepared to explore and exploit the interrelations of incongruent concepts from different cultures, as they benefit from higher integrative complexity to acknowledge competing perspectives on the same issue (i.e., differentiation) and to forge conceptual links between these perspectives (i.e., integration; Suedfeld, Tetlock, & Streufert, 1992; Tadmor & Tetlock, 2006; see also Leung et al., 2018). The capacities to differentiate and integrate are conducive to expanding the conceptual boundaries of an existing concept by combining it with other seemingly irrelevant concepts (T. Ward et al., 1997). This so-called “creative conceptual expansion process” can even strengthen one’s general ability to think creatively (Leung & Chiu, 2010).

In other work, Gocłowska and Crisp (2014) described the bicultural identity experience in terms of depth, dual engagement, and a combination of culturally distinct identities. Adhering to bicultural identities entails developing a deeper relationship or stronger identification with two cultures that often have sufficiently different norms and values; when combined, these characteristics trigger higher levels of cognitive flexibility and set breaking (Godart, Maddux, Shipilov, & Galinsky, 2015; Maddux, Bivolaru, Hafenbrack, Tadmor, & Galinsky, 2014; Morris, Mok, & Mor, 2011; Tadmor et al., 2009). Gocłowska and Crisp (2014) theorized a temporal continuum framework of adjustment in which individuals with bicultural identities would progressively master cognitive skills from learning to (1) alternate between dual identities in a way that facilitates mental frame switching and

set breaking at an early stage of cultural adaptation (alternation; e.g., Friedman et al., 2006; Hong et al., 2000; Nijstad, De Dreu, Rietzschel, & Baas, 2010) to (2) integrate incongruent cultural perspectives in a way that reconciles conflicting values and cognitions (integration; e.g., Huang & Galinsky, 2011; Saad, Damian, Benet-Martínez, Moons, & Robins, 2013; Tadmor, Galinsky, & Maddux, 2012), and to (3) eventually develop a broadened, inclusive, and superordinate sense of self-definition that increases receptivity to recruiting ideas from a wider scope of cognitions, norms, and values at a later adaptation stage (inclusion; e.g., Amiot et al., 2007; Gaertner et al., 2000; McFarland, Brown, & Webb, 2013).

Empirical evidence abounds supporting the creative benefits of multicultural knowledge and multicultural identity. For example, correlational studies demonstrated that individuals spending a longer time living in a foreign country performed better in creative idea generation or insight tasks (Leung & Chiu, 2008, 2010; Maddux & Galinsky, 2009). Experimental manipulation studies further confirmed the causal link between joint culture activation and creative processes and outcomes (Leung & Chiu, 2010). In the first experimental study investigating the creative benefits of multicultural exposure, Leung and Chiu (2010) had American students participate in a cultural induction session in the laboratory that involved watching a 45-minute slideshow depicting different representative elements of one or two cultures. They found that randomly assigned participants who were exposed to American and Chinese cultures jointly or in a hybrid manner (e.g., an art piece made up of a ceramic-coated Coca-Cola bottle attached to a lively dragon figure) generated more creative stories and analogies than those in the single-culture activation conditions (exposure to either Chinese or American culture) or the no-cultural-exposure control condition. Notably, the analogy task was done about a week after the cultural induction session, which suggests that creative benefits from joint culture activation can persist, at least after a short delay.

In terms of creative processes, research indicated that individuals with richer multicultural experiences are more inclined to sample ideas from foreign (vs. local) cultures for creative idea expansion and to spontaneously retrieve unconventional concepts from memory, which are cognitive processes essential for creative thinking (Leung & Chiu, 2010).

In addition to cognitive mechanisms, Cheng, Leung, and Wu (2011) examined the role of emotions in creativity, based on the propositions that (1) negative emotions can be induced by cognizing the juxtaposition and the accompanied dissonance of seemingly conflicting ideas from dissimilar cultures, (2) negative emotions facilitate cognitive complexity (e.g., Forgas, 2007; Isen, Means, Patrick, & Nowicki, 1982; Sinclair, 1988), and (3) higher levels of cognitive complexity are conducive to creative capability (Tadmor et al., 2009). Their findings with Singaporean Chinese students replicated prior findings that joint culture activation improved creativity, and offered partial support for the proposed mediation link that dual (vs. single) cultural exposure reduced the degree of positive emotion, which in turn promoted greater creative flexibility. In another study that recruited a Taiwanese sample (that had relatively fewer multicultural experiences and a stronger degree of cultural ambivalence compared to Singaporeans), negative emotions significantly mediated the link between local–foreign cultural exposure and higher creative performance. This study further compared the effects of exposure to a self-relevant local (Taiwanese) culture and a foreign (American) culture versus two foreign cultures (Indian and American cultures). Exposure to two foreign cultures did not produce creative benefit, but exposure to the local and foreign cultures did. The significance of this research is twofold. First, the findings suggest the creativity-enhancing property of encountering a foreign culture while maintaining contact with a self-relevant local culture. Second, it offers a novel perspective to approach the relationship between emotions and creativity. This research does not discount the creative benefits of positive emotions (e.g., Baas, De Dreu, & Nijstad, 2008). Rather, it showcased the possibility that in culturally mixed encounters, negative emotions might be more useful than positive emotions in motivating the reconciliation and synthesis of seemingly incompatible ideas from two cultures, particularly if one is local (self-relevant) and the other is foreign. As the researchers suggested, it would be highly illuminating for future research to conduct a more fine-grained analysis to distinguish negative emotions that may catalyze creativity (e.g., conflicted, confused, puzzled) from those that may paralyze creativity (e.g., fear, anger, disgust) in intercultural contexts.

Research evidence has accumulated to enrich our understanding of the nuances of the multicultural experience–creativity relationship by

examining how it could be modulated by other variables such as epistemic closure (Leung & Chiu, 2010), existential anxiety (Leung & Chiu, 2010), multicultural learning (Maddux, Adam, & Galinsky, 2010), cultural distance and comparison mindsets (Cheng & Leung, 2013), perceived ambient cultural disharmony (Chua, 2013), and multicultural engagement (Maddux et al., 2014).

Other research examined the creative correlates of dual cultural identities. Cheng and colleagues (2008) found that Asian Americans and female engineers with higher BII, not lower BII, performed more creatively in tasks that were identity relevant (e.g., developing fusion dishes using both Asian and American ingredients, designing a product for female users). By simultaneously accessing knowledge systems from two compatible social identities, individuals with higher BII exhibit higher creativity in tasks that draw on identity-related knowledge domains (see also Benet-Martínez et al., 2006, for a related study on BII that showed a different effect). Relatedly, in another study, bicultural individuals who identified with both cultures (i.e., integrationist), but not those who identified with only one culture (i.e., assimilationist or separationist), displayed higher integrative complexity and creativity manifested in both the laboratory and the workplace (more innovation, higher promotion rates, and more positive reputations at work; Tadmor et al., 2012). Integrative complexity mediated these positive outcomes of dual identification. Interestingly, increased levels of integrative complexity, innovation, and professional success were also observed among marginal individuals who identified with neither culture, although these positive outcomes were lower than those for the integrationists.

Bilingualism

Biculturalism or multiculturalism is reciprocally linked to bilingualism or multilingualism, for bicultural/multicultural experience gives people an advantage in acquiring competency in a second language and bilingual/multilingual experience socializes people into different cultural systems of thoughts (Loewenstein, [Chapter 9](#), this volume). Very often, second-language learning is part of the multicultural education curriculum (Reyes & Vallone, 2007). With two languages operating in tandem on a

regular basis, greater attentional and inhibitory control is demanded of bilinguals to suppress coactivation of the nontarget language (Starreveld, De Groot, Rossmark, & Van Hell, 2013). Regularly exercising these cognitive faculties was hypothesized to bring about superior executive control (Bialystok, 2009) and creative functioning (e.g., Kharkhurin, 2009). These cognitive advantages might also be traced to some neural architectural differences that develop between bilinguals and monolinguals (Abutalebi & Green, 2007).

An exhaustive review of the bilingualism research is beyond the scope of this chapter (for reviews, see Hilchey & Klein, 2011; Kroll & Bialystok, 2013; Paap, 2014; Ricciardelli, 1992; Valian, 2014). Instead, we briefly discuss some controversies centering around the effect of bilingual benefits on executive control and creativity, and some ways to dissociate bilingual benefits from bicultural benefits in cognitive functioning through experimental studies.

Support for the association between bilingualism and creativity is generally positive. According to Ricciardelli's (1992) review, 20 out of 24 studies demonstrated support for bilinguals' greater creativity. However, they are inconsistent about the domains in which it is observed—sometimes in terms of fluency, other times flexibility, still other times originality, and so on (Kharkhurin, 2008, 2009, 2010, 2011; Leikin, 2012; Leikin & Tovli, 2014). Due to variations in study methods, it is difficult to disentangle whether the sample, measurement, or other issues accounted for such inconsistencies, though the general notion that bilinguals have a creativity advantage seems robust.

There is some support for a bilingual advantage in executive control (for research on the benefits of bilingualism, see Bialystok, Craik, & Luk, 2012; Bialystok & Viswanathan, 2009; Carlson & Meltzoff, 2008; Hilchey & Klein, 2011; Martin-Rhee & Bialystok, 2008). However, conclusions remain equivocal given the substantial number of mixed (Kovács & Mehler, 2009; Luk, De Sa, & Bialystok, 2011; Valian, 2014) or null findings (Kousaie & Phillips, 2012; Paap & Greenberg, 2013; Paap, Johnson, & Sawi, 2014). Such inconsistency may be related to the different tasks used to assess executive function, differences between samples (particularly with respect to age), and so on (see Paap et al., 2014; Valian, 2014). Notably, more consistent evidence was found among older adult samples, suggesting that bilingual competency provides cognitive stimulation that mitigates decline in executive function

in elderly people (Bialystok, Craik, Klein, & Viswanathan, 2004; Gold, Kim, Johnson, Kryscio, & Smith, 2013; Zahodne, Schofield, Farrell, Stern, & Manly, 2014).

Adding to the murkiness is the question of whether advantages derive from respondents' bilingualism or their biculturalism (for notable exceptions, see Bialystok & Viswanathan, 2009; Tran, Arredondo, & Yoshida, 2015; Yang, Yang, & Lust, 2011). As one might expect, experimental studies on the effect of learning a second language are relatively rare. However, such designs can help identify the causal effects of second-language learning as opposed to simultaneous second-language and second-culture learning.

To shed light on the bilingualism–executive control or the bilingualism–creativity causal link, a longitudinal design with a control group is the most sought after, but relatively rare, methodology (for exceptions, see Blom, Kuntay, Messer, Verhagen, & Leseman, 2014; Burkholder & Harlow, 2003; Ljungberg, Hansson, Andres, Josefsson, & Nilsson, 2013). Individuals who voluntarily learn a second language can be progressively assessed for their executive control or creativity before the language program commences (baseline) and over the course of advancing in the program. Bilingual advantage would be supported by incremental performance growth between the baseline and subsequent tests in the language-learning group relative to the control group. In the school context, where learning a second language is mandatory, the switching replications design can be employed, with one group of students being randomly assigned to take the language course earlier (e.g., one semester ahead) than another group. Post–language course assessment should show comparable performance boosts for both groups if bilingual advantage exists.

COSMOPOLITANISM IN THE MULTICULTURAL WORLD

Despite the upsurge of research interests in multiculturalism, until recently, psychologists have remained relatively slow in undertaking empirical inquiries into related topics such as globalization and cosmopolitanism (Arnett, 2002; Bandura, 2001; Chiu, Gries, Torelli, & Cheng, 2011). Multiculturalism celebrates ethnocultural diversity and offers a welcoming

sociocultural context for cultural omnivores to embrace a multitude of practices, traditions, cuisines, and music in a multiethnic community. Although an orientation toward cosmopolitanism very often aligns with these multicultural ideals, Yarram and Shetty (2014) differentiated the two constructs by arguing that “multiculturalism is based on preserving inherent differences while cosmopolitanism is based on bridging them” (p. 47). In this light, Yarram and Shetty argue that cosmopolitanism might be conceived of as a value-laden reaction to multiculturalism—whereas multiculturalism acknowledges cultural diversity, cosmopolitanism idealizes the diversity itself so as to embrace, respect, cherish, and unite differences.

Cosmopolitanism and Its Relations to Related Constructs

Cosmopolitanism and Globalization

Cosmopolitanism is not a new concept; the term “cosmopolitanism” was first coined by Diogenes of Sinope (c. 412 B.C.E.) in Ancient Greece, who declared himself a cosmopolitan or “Kosmopolitês” in Greek, meaning “citizens of the world.” During the Enlightenment period, philosophical discussions of cosmopolitanism resurged due to ever-increasing expeditions across the globe, expanding national boundaries of powerful empires, the rise of transnational trade and the accompanying capitalism, as well as the rising popularity of discourses that advocated open-mindedness, human rights, and impartiality (*Stanford Encyclopedia of Philosophy*, 2013). Cosmopolitanism is highly intertwined with globalization. Broadly defined as a process of interaction and integration among the people, companies, and governments of different nations, “globalization” involves global flows of goods, services, ideas, technologies, cultural forms, and people (Chiu et al., 2011; Kellner, 2002). As such, globalization speeds up the transnational circulation of ideas, languages, and popular cultures, and facilitates the inflow of capitalist values, neoliberal economic thought, and instrumental rationality into many regional economies (Leung, Qiu, & Chiu, 2014). As discussed here, globalization and cosmopolitanism are related but refer to

distinct phenomena: “globalization” is about the state of markets, travel, and exchange; “cosmopolitanism” refers to a state of mind.

Notably, globalization is neither a necessary nor a sufficient condition for cosmopolitanization (Woodward, Skrbis, & Bean, 2008). It is common for people to experience globalization, but not all of them will assume a cosmopolitan outlook and appreciate cultural diversity. If they believe that the hegemonic dominance of the global culture would erode the authenticity or integrity of local cultures, such perceptions might spur contested, exclusionary reactions to withdraw from contacts with foreign cultures and to recede back into their native culture comfort zone (Chiu & Cheng, 2007, 2010; Chiu & Hong, 2006). Contrariwise, people do not necessarily have to encounter globalization upfront in order to develop a cosmopolitan worldview (Kanter, 1995). They might be geographically immobile but have notable opportunities to come into contact with a variety of cultures through traditional and new media such as social networking sites (e.g., Facebook, Twitter) and online communication platforms (e.g., Skype, Whatsapp, WeChat, Second Life virtual world; Larsen, Urry, & Axhausen, 2006).

Cosmopolitanism, Nationalism, and Localism

It is commonly presupposed that the exclusionary, parochial nature of nationalism does not resonate well with cosmopolitanism (Mazlish, 2005; Rundell, 2004). In sociology, Merton (1949, 1957) first made popular and contrasted the notions of localism and cosmopolitanism through the study of influential persons in a small American town during World War II. Cosmopolitan and local people differ in their identity orientation to reach beyond the local context (or not). Cosmopolitan elites are often described as well-connected internationally but disconnected locally (Lasch, 1979).

However, cosmopolitanism might not run as counter to nationalism and localism as initially theorized by some researchers (e.g., Beck, 2000, 2002; Castells, 1996; Nussbaum, 1994). Some scholars have argued that a national home could in fact provide a secure base to practice cosmopolitan openness (Black, 2006; Cheah, 2006); one might be a “cosmopolitan patriot” who shows love and pride in one’s nation and at the same time enthusiastically

maintains a broad cosmopolitan outlook exposed to different ways of living (Appiah, 1997). In a small interview study with a convenience sample of Australians, some people endorsed nationalism and cosmopolitanism simultaneously (Brett & Moran, 2011).

In a similar vein, mobile cosmopolitans were found to maintain both local and national bonds (Doyle & Nathan, 2001). Cosmopolitanism and localism are not an “either–or” option, but possibly a both . . . and . . . combination that allows people simultaneously to use local and global resources to take advantage of both local involvements and globally dispersed connections (Gustafson, 2009; Pollini, 2005; Urry, 2003). A survey with 2,804 Swedish respondents found that frequent international travelers who were considered cosmopolitans were even more locally involved than nontravelers in their social networks and organizational activities, although they superficially appeared to be less local in their cultural preferences (e.g., less interest in Swedish holidays and local news). In a study on second-generation Albanian-origin teenagers in Tuscany, Vathi (2013) found that they had transnational ties that went beyond the host and home countries. In this light, Vathi referred to “glocalized cosmopolitanism,” a concept that operates on a cosmopolitan–local continuum to describe the coexistence of cosmopolitan and local identities (Roudometof, 2005). Overall, though cosmopolitans may be less chauvinistic and jingoistic, evidence is not supportive of the common assumption that cosmopolitans are less nationalist, less local, or more disconnected from their local communities.

Cosmopolitanism and Global Identity

“Cosmopolitanism” is often used interchangeably with “global identity,” defined as the tendency to see oneself as a world citizen (Leung et al., 2014). However, there are profound differences between the two. Cosmopolitan individuals appreciate the manifestations of cultures in their many forms and advocate preservation of the authenticity of indigenous cultures (Beck, 2006; Szerszynski & Urry, 2002, 2006). Globally identified individuals, on the other hand, romanticize the ideals of removing cultural borders and building a global village. In the political realm, they support global governance and transnational institutionalization; in the economic realm,

they eschew trade barriers. Esperanto would be the dream of a globalist, not a cosmopolitan. In other words, cosmopolitanism respects and cherishes cultural heterogeneity, whereas global identification supports breaking down cultural boundaries that are seen as arbitrary (Leung et al., 2014). Whereas cosmopolitans celebrate multiculturalism, globalists believe in the global (capitalist) melting pot.

The Development of a Three-Dimensional Cosmopolitan Orientation Scale

Cosmopolitanism is a relatively elusive concept. Broadly speaking, it has been conceptualized as a set of attitudes, values, and practices (Vertovec & Cohen, 2002; Woodward et al., 2008), a learnable skill (Thompson & Tambyah, 1999), a personality trait (Cannon & Yaprak, 2002), a perspective or state of mind (Hannerz, 1996), and a political project to realize the benefits brought about by ethnic diversity, global governance, and transnational institution building (Mann, 1997; Vertovec & Cohen, 2002).

According to Leung, Koh, and Tam (2015), so far, mainly theoretical writings have informed the study of the core attributes of cosmopolitanism (with exceptions; e.g., Olofsson & Öhman [2007] and parts of Norris & Inglehart's [2009] country-level Cosmopolitanism Index). To fill the gap, they developed a Cosmopolitan Orientation Scale (COS) to measure three essential qualities of being a cosmopolitan individual (cultural openness, global prosociality, respect for cultural diversity). Systematic tests were done to confirm the psychometric properties of the scale with samples from Singapore, Australia, and the United States. An empirically validated scale should be useful for contributing to more systematic investigations into cosmopolitanism (Cleveland, Erdoğan, Arıkan, & Poyraz, 2011; Skrbis, Kendall, & Woodward, 2004; Thompson & Tambyah, 1999).

The first dimension of the COS, and perhaps the most defining core seen in existing measurements (e.g., Cleveland, Laroche, & Papadopoulos, 2009), is *cultural openness* (Hannerz, 1990; Roudometof, 2005; Szerszynski & Urry, 2002). Cosmopolitans have an outward stance of being ecumenical and open, both intellectually and aesthetically, toward divergent cultural experiences (Beck, 2002; Hannerz, 1990). They are usually culturally

competent in interacting with, participating in, and understanding different cultures (Pichler, 2011). They are regular travelers who can easily feel at home when abroad (Konrád, 1984). As they are highly receptive to engaging with and learning from people, places, and experiences that belong to other cultures, they are often open-minded intellectuals, or so-called “cultural omnivores,” who seek mental stimulations through new cultural encounters (Brett & Moran, 2011; Lizardo, 2005).

The second dimension that has been theorized, but seldom empirically measured is *global prosociality*. Cosmopolitans tend to hold the belief that morality should be rooted globally, not locally, and that basic rights and justice should be universally respected for all people, as they are equally human (Kant, 1991; Varsamopoulou, 2009). Aspiring toward a sense of universal affiliation with humankind (Bilsky, Janik, & Schwartz, 2011; Pichler, 2009), cosmopolitan individuals advocate a prosocial orientation to promote benevolence and generosity, and shun social dominance or inequality. They see the value of promoting feelings of collective moral obligation to build a better world for all and to safeguard the human future (Falk, 2002; Yeğenoğlu, 2005). Of import, cosmopolitan people tend to place precedence on intensity of needs over proximity of needs and share concerns that transcend local issues (Contorno, 2012; Nussbaum, 1994; Pollini, 2005).

The third dimension concerns displaying *respect for cultural diversity*. Cosmopolitan individuals recognize, respect, and consume cultural differences (Szerszynski & Urry, 2002, 2006) to the extent that they afford a “delight in difference” (Hannerz, 1990). They presuppose positive attitudes toward seeking out cultural differences rather than uniformity (Hannerz, 1996). As highly competent cultural navigators (Hall, 2002), cosmopolitans often serve as “cultural brokers and gatekeepers” to interlink cultures and preserve authentic cultural practices (Hannerz, 1992, p. 258).

Interestingly, the notion of cosmopolitanism embodies a seemingly paradoxical meaning, as *cosmo* refers to nature’s “universal” order and *polis* refers to a society’s “different” order (Ribeiro, 2001). According to Leung and colleagues (2015), this paradox can be resolved if we interpret cosmopolitan individuals as using the protection of minimal universalistic norms (Beck & Sznaider, 2010) as the prerequisite for respecting different cultural forms and expressions (but see Miller, Wice, & Goyal, [Chapter 16](#), this volume, for

why this is not a simple matter). Therefore, global prosociality and respect for cultural diversity go hand in hand to epitomize a cosmopolitan ideal that seeks to reconcile and unite similarities and differences (Ribeiro, 2001) and to mediate between the familiar and the foreign (Levy, Beechler, Taylor, & Boyacigiller, 2007).

Cosmopolitan Orientation, Environmentalism, and Other Prosocial Behaviors

Many known factors such as personality traits (e.g., Openness to Experience; Markowitz, Goldberg, Ashton, & Lee, 2012), social demographics (e.g., age, gender, party affiliation; Dunlap, 1975; Gifford & Nilsson, 2014; Malkis & Grasmick, 1977; McEvoy, 1972), and value or belief systems (e.g., postmaterialist values, belief about humans' connection to nature; Inglehart, 1995; Tam, 2013) have been used to explain individuals' proenvironmental behaviors. Whereas globalization has had substantial (and typically negative) impacts on the environment (see Donaghy, 2012; Finger, 1994; Najam, Runnalls, & Halle, 2007; Rohrschneider & Dalton, 2002), the cosmopolitanism largely afforded by globalization might counteract these impacts (Leung et al., 2015). Yet accounting for individual variability in proenvironmental acts is seldom approached in terms of the cosmopolitan dimension.

It has been theorized that a cosmopolitan orientation is linked to heightened environmental concern through at least two paths (Leung et al., 2015). The first path concerns *knowledge acquisition*, which presupposes that cosmopolitans are more aware of or have a higher chance to encounter environmental crises firsthand. They have acquired substantial knowledge about the global scope of environmental problems and environmental protection practices that prompt them to readily act to combat environmental degradation (Finger, 1994; Najam et al., 2007; Rohrschneider & Dalton, 2002). The second path concerns *global interdependence*, which presupposes a global sense of moral obligation to mitigate damage to the environment. This frame of mind strengthens people's identification with the human race (see McFarland et al., 2013; McFarland, Webb, & Brown, 2012) and a sense of global (vs. local) place attachment (see Devine-Wright,

2013; Devine-Wright, Price, & Leviston, 2015). Thus, it invigorates a culture of global humanitarian concern to alleviate aversive environmental impacts on fellow human beings, regardless of nationalities (Donaghy, 2012).

Controlling for generalized environmental worldviews, motivations, and beliefs, results from Leung and colleagues (2015) revealed that the composite COS and, in particular, the dimension of global prosociality add unique power in predicting proenvironmental behaviors among the Singaporean, Australian, and American samples from two studies. Consistent with this, another study examined feelings of global belongingness, a construct highly relevant to a cosmopolitan orientation, and showed that participants from the United States, China, and Taiwan who scored higher in Global Belonging displayed significantly more environmentally sustainable behavior (Der-Karabetian, Cao, & Alfaro, 2014).

We encourage more research to explore the COS (Leung et al., 2015) as a tool and to unpack the understudied link between individuals' cosmopolitan orientation and their approach toward pressing issues occurring on a global scale, such as global immigration and xenophobia. Examining cross-national variations in cosmopolitan orientation might also be useful for identifying policies relevant to how different nation-states can manage and regulate a host of global challenges. For example, it could be useful to examine how a cosmopolitan orientation can be developed and leveraged into high levels of globally prosocial behavior.

CONCLUDING REMARKS

Multiculturalism research has flourished in the last decade. Because emerging issues and events have rippling implications across cultural borders, the study of multiculturalism will be concerned with increasingly complex questions and agendas. Multiculturalism is multifaceted. It provides an ideological foundation and informs policymaking for many nations. It presents individuals with opportunities to attain indispensable skills and creative capital through cultural learning, cultural adaptation, and second-language acquisition. It provides the cultural backdrop for individuals to develop their self-identity. It (along with the highly-related

cosmopolitan mindset) suggests solutions to timely global problems such as environmental sustainability and managing immigration. It creates both challenges and opportunities for practices of cultural diversity and intercultural inclusion in everyday living. Above all, multiculturalism represents well many people's way of life in the global world.

This rosy outlook aside, it requires enormous efforts to make multiculturalism work. Diversity may imply division, tension, and vulnerability. Multicultural nations should not take racial and religious harmony for granted, but seek to keep a delicate balance between respecting differences and establishing a sense of togetherness. Multicultural individuals are likely to have to overcome the challenges and distress brought about by cultural clashes before they can harness the many benefits of being a multicultural.

CHAPTER 22

Cultural Psychology of Money

Dov Cohen, Faith Shin, and Xi Liu

We cover how people think about money and markets, focusing on three areas: (1) We describe the workings of money in poor communities of the developing world, the challenges poor people face, and interventional “nudges” to help deal with those challenges; (2) we examine basic issues about people’s conceptions of money, trade, and debt, exploring their connection to interpersonal and intergroup relations; (3) we discuss people’s beliefs about markets, highlighting some forces leading to bubbles and crashes. The theme of “rationality” runs throughout. However, rationality is not a unitary construct, and conditions heightening rationality on one dimension often undermine it on others. Thus, scarcity enhances the cold rationality of identifying trade-offs but makes it harder to resist hot emotions that tempt us to behave against our long-term interests. In section two, we note that money itself tries to “rationalize” relations between people. But, as markets scale up, they create (1) intermediary (“middlemen”) roles that derive from and inflame ancient, irrational prejudices and (2) intermediating institutions that can turn cultural values on their head. In the section on markets, we describe how “rational” came to mean *unpredictable* and how innovations designed to hedge against risk instead became so byzantine that they led to huge losses. We also explore contradictory attitudes of individualists, who believe in the wisdom of the market yet are (over)confident that they can beat it.

It has been said that more people have made fools of themselves writing about money than about any other topic. We attempt this fool’s errand here. More precisely, we write about the way people think about money and markets. Our chapter offers a selective review, focusing on three areas. We

start with work in the developing world on how poor people use money, the challenges they face, and interventions that might help them overcome these challenges. Then we step back and consider basic issues about people's conceptions of money, trade, and debt, exploring how these are tied up with interpersonal and intergroup relations. Finally, we consider the topical question of how people think about markets and some of the cultural-psychological forces leading to bubbles and crashes (see brief chapter summary in [Table 22.1](#)).

TABLE 22.1. Chapter Summary: Three Sections on the Cultural Psychology of Money

The chapter's three sections explore the way people think about money and markets. The theme of "rationality" runs throughout. However, rationality is not a unitary construct, and it seems that conditions that lead to greater rationality in some senses of the word also lead to less rationality in other senses.

Workings of money in poor communities

1. Scarcity enhances the cold rationality of economic reasoning, while also making it harder to resist hotter, affective influences and focus on long-term goals.
 2. In the developing world, experiments by economists illustrate the promise of using channel factors or "nudges" to help people turn good intentions into good behavior.
 3. Nudges can make human foibles—tendencies to procrastinate, avoid decisions, and do what is easy—work to people's benefit rather than detriment.
 4. The developed world is full of invisible nudges, but systems and institutions in the developing world often place the greatest demands for rationality on those lacking the stability and security conducive to long-term thinking.
 5. Studies have also led to surprising findings about
 - a. How much the poor in the developing world are able to save and manage risks in the face of trying circumstances.
 - b. The huge importance (in terms of spending, community standing, and perhaps even personhood) that festivals and life cycle events play in the lives of the poor, whose interdependence can act both as a crucial safety net and as a drain on resources.
 - c. The relatively slight positive effects of microfinance. Despite the entrepreneurial energies of the poor, stable employment seems more suited to producing the sustained income and "mental space" that allow people to plan for their well-being and that of their children.
-

Money, trade, and markets

1. Money and markets attempt to "rationalize" relations between people, making relations more efficient, equitable, interchangeable, and rule-bound.
2. Money affords a way of interacting in which parties are free to exchange, settle their debts, and walk away.
 - a. This contrasts with societies operating on a principle whereby relationships should always be slightly out of balance, thus ensuring that cycles of reciprocity will continue.
 - b. "Gift" giving need not always be benevolent and may be done with many different intents, including putting another in one's debt. The modern Western notion of a "free gift" is relatively peculiar.
3. Markets can inculcate a universalistic ethic of fair play among strangers. However, as they scale up, markets can also reify and inflame irrational prejudices, for example, against "middleman" minorities, whose roles are hard to understand and often seen as parasitic.
4. Markets often express the values of a culture. However, as they scale up, intermediating institutions also develop and can sometimes pervert attitude-behavior relations. As an example:
 - a. Protestantism turned Catholicism's historical stigma against lending and usury on its head, transferring stigma to the borrower.
 - b. Stigmatization of borrowing led to laws and practices protecting lenders.

- c. Laws and practices protecting lenders increased the supply of money to be loaned and hence the amount of debt households took on. Historical antidebt attitudes in part led to more household debt in Protestant countries.

Bubbles and crashes

1. Experimental economics suggests that markets can be very efficient in distributing nondurable goods, but that markets for assets are often unstable because they invite speculation.
 2. Over several hundred years, crashes and bubbles have been semiregular occurrences, often initiated by a cultural narrative about an innovation that supposedly makes this time different.
 3. In the most recent U.S. crisis, financial innovations that were supposed to decrease risk became so complicated, tangled, and opaque that few understood the huge risks they were actually taking.
 4. Crises also arise because of a narrative about easy money—a belief revealing a contradiction in Americans’ (and individualists’) beliefs about “The Market.”
 - a. Americans believe in the Solomonic wisdom of markets as rational, fair, and efficient.
 - b. Yet they also believe—to their own detriment—that they can beat the market by outsmarting their peers. Individualism is associated with trading volume, volatility, and the market anomaly of “momentum” effects, consistent with this peer-comparison overconfidence.
 - c. Some of individualism’s core features (e.g., a contrarian attitude) should prevent bubbles, but overconfidence and institutional pressures offset a portion of this.
-

In these topics, psychologists will recognize much that traditionally has interested them: issues of independence and interdependence; prejudice; ideas about fairness, cooperation, and competition; the power of the situation and the crucial importance of channel factors in turning attitudes into behavior; cognitive heuristics and biases; conflicts between hot (affective) versus cold (cognitive) systems; social influence; reciprocity; and so on.

However, because the topic is money, and money is traditionally the purview of economists, one theme keeps recurring: rationality.

On the one hand, it seems a completely straightforward assertion that people, more or less, have generally realistic appraisals of the world and act on those appraisals to produce outcomes that they think are best. At the collective level, it seems straightforward that we have generally moved to a more “rationalized” social order, as opposed to one based on tradition, magic, or charismatic authority (Weber, 1905/1958, 2013). However, one issue the review highlights for us is the extent to which rationality is more like an agglomeration of constructs as opposed to a single unitary ideal, and that conditions enhancing rationality in one sense of the word often undermine it in another.

In the three sections of the chapter (on poverty and the developing world, conceptions of money and credit, and markets and crashes), moves toward rationality on some dimensions seem to be accompanied by moves away from it on other dimensions. Thus, in work on poverty and affluence, scarcity of resources enhances a cool, cognitive rationality of focusing on key issues and trade-offs, while it also undermines our ability to control hotter, affective impulses that lead us to act against our best interests. Meanwhile, effective interventions often play on our irrational tendencies (to procrastinate, to engage in superstitious mental accounting, to limit our search and disengage from difficult decision making) to produce actions that are in our long-term best interests.

In terms of social evolution, moves toward more “rational” economic arrangements—in terms of specialization, trade, the allocation of credit—have run up against human intuitions, superstitions, and prejudices to produce more virulent hatreds. Furthermore, as societies scale up, attitudes about debt and credit have led to the creation of intermediating institutions that seem to have inverted normal attitude–behavior relationships, leading to behaviors that are the *opposite* of those cultural attitudes.

Finally, concerning markets, the very definition of rationality—in lay and, until recently, professional understanding of the term—seems to be in question, such that “rational” and “predictable” are now seen as opposites. Furthermore, the ability to create complexity and “manage” risk has created instruments that are far too complicated for most people to understand and predict; hence, they may make financial situations more risky rather than less. Meanwhile, paradoxical attitudes arise such that, for example, individualists who have the greatest faith in the Solomonic wisdom of the market also believe they can beat it. Markets in individualist countries should be less susceptible to various “irrational” behaviors but in some cases exhibit more of them.

In jest, one might propose there is some cosmic equivalent to Newton’s Third Law that for every move toward rationality, there is an equal and opposite move toward irrationality. More likely, however, our conception of rationality as a unitary construct is flawed—there are limits to humans’ cognitive abilities that are very difficult to plan around, and evolution toward more “rational” social arrangements occurs, but its movement is fitful.

In the developed world, it is striking how much does *not* depend on our optimal decision making. Modern Westerners are obsessed with rationality. Yet much of the rationality that is required has been outsourced, embedded in institutions and invisible nudges that keep people on the right track (or at least away from terrible outcomes). As we note in the first section, these are advantages that the poor of the developing world do not have as they confront decisions about money, resources, and health that are far more consequential than our own.

MONEY RICH AND POOR: WORKINGS OF MONEY IN POOR COMMUNITIES

As researchers at universities, we mostly study students who come from, or are headed to, the North American or European middle- and upper-middle class. In one of the most exciting new areas of work, however, researchers study a very different population, examining the very poor in the United States and around the world. Below we note some striking findings from experimental work, diary studies of people in the developing world living on \$2 a day, and some randomized controlled trials for interventions with these populations.

Scarcity and Rationality

Psychologists have often been gadflies for economists. Most economic models start by assuming people are rational. Psychologists (and behavioral economists), however, have been cataloguing instances in which this assumption falters—both in terms of what Frank (2005) called “departures from rationality without regret” (when people act against self-interest narrowly defined because of their sense of justice or virtue) and “departures from rationality with regret” (when people make bad choices due to context effects that should logically be irrelevant).

Psychologists and their participants usually live in a world of plenty, and their theories and phenomena reflect this. As Shah, Shafir, and Mullainathan (2015) point out, though, economics “is built on the (correct) assumption

that humans navigate a world of scarcity and regularly make trade-offs” (p. 411). As a consequence, when researchers examine poor people for whom scarcity is very real, or examine people put in a scarcity mindset, their choices align more with some classic tenets of economic rationality. They think more in terms of opportunity costs (e.g., if they buy a sports ticket for \$20 and could resell it for \$75, they say it feels like it costs them \$75, not \$20, to go to the game; Mullainathan & Shafir, 2013). They evaluate goods more consistently and are more attuned to utility rather than context, being unwilling to pay more for a beer bought from a fancy resort versus a run-down grocery store (Shah et al., 2015). They think in terms of trade-offs rather than proportions, being about equally likely to drive across town to save \$50, regardless of whether the discount is on a \$300, \$500, or \$1,000 purchase (Shah et al., 2015). They *may* be less likely to heuristically assume that buying in bulk is cheaper (Binkley & Bejnarowicz, 2003). And they make more rational choices on tasks, even as a variety of irrelevant context effects throw off their wealthier counterparts (Shah et al., 2015).

All choices involve trade-offs; but as Shah et al. (2015, p. 411) note, “when people experience sufficient abundance, those trade-offs recede from attention,” whereas conditions of scarcity prompt people to construct preferences in line with economic predictions. Some classic behavioral economics irrationalities may just be part of the human condition. For example, anchoring and adjustment effects seem to hold for poor and rich alike. And even monkeys show loss aversion, preferring an experimenter who offers one piece of fruit but occasionally gives two over an experimenter who offers two pieces of fruit but occasionally takes one away (Santos & Rosati, 2015; cf. Silberberg et al., 2008)—though it is unknown whether monkeys’ preferences would hold under conditions of extremely limited resources. Other irrationalities, such as those mentioned earlier, may be a product of living in a world of plenty rather than scarcity.

Scarcity and Irrationality: Tunneling and Temptation

One should not suppose that poor people always make more rational decisions. The examples above derive from rather cold cognitions. When cognitions turn hotter, however, scarcity can make one more vulnerable to

irrational, short-term thinking. Much of the work of Mullainathan and Shafir (2013) has explored how scarcity leads to a focus on the limited resource and can create “tunneling,” in which the goal of getting the limited resource leads one to ignore other considerations and therefore make choices satisfying short-run goals at the expense of long-run outcomes. Most pernicious is the tendency to borrow against the future. The booming business of payday lending attests to this, as people wind up paying 400% annualized interest or more (e.g., on a 2-week loan that charges \$15 per \$100 advanced) and often end up compounding the cost by having to roll over the loan when repayment is due. People are not poor because they make bad decisions, Mullainathan and Shafir argue; they make bad decisions because they are poor.

Experimental studies show how those short on money tend to overborrow. And to demonstrate the more general point about scarcity producing tunneling, they also show how, in experimental games, those who were short on *time* tended to overborrow against the future, bargaining for a small gain of time now, even though it would cost them a lot of time later (Shah, Mullainathan, and Shafir, 2012). The tighter a resource (time or money) became, the more borrowing against the future increased in ways that hurt participants’ ultimate payout in the game (compared to resource-rich participants, who did not have to borrow, and resource-poor participants in another condition, who could not borrow).

Scarcity, Mullainathan and Shafir (2013) argue, engenders tunneling. The intense focus on the scarce resource creates a “bandwidth tax,” reducing one’s ability to use mental resources for other purposes. On a few cognitive tasks that Mullainathan and Shafir administered, poor and rich people in the United States performed similarly in control conditions. However, just raising money concerns (by having people think about a \$3,000 car repair vs. a \$300 one) reduced the performance of poor subjects on tasks such as Raven’s Progressive Matrices test or executive control tasks requiring inhibition (e.g., go/no-go tasks). Similar effects held for farmers in India, whose performance was worse preharvest (when they had little money) compared to postharvest (when they were relatively wealthy) (see also Tomm & Zhao, 2016; Zhao & Tomm, 2017).

That the bandwidth tax reduced people’s ability to inhibit is particularly striking. Living on the edge means constantly living with temptation and

having to say no. And that constant but unsated temptation can be its own undoing (Baumeister & Tierney, 2012). Economists George Akerlof and Robert Shiller (2015) talk about “1 percent moments.” “Even if we are careful 99% of the time, the remaining 1%, when we act as if ‘money does not matter,’ can undo all that prior rectitude” (p. xiii). Enough damage can be done in 1% moments to more than compensate for the austerity we show 99% of the time. Anyone who has been on a diet knows a parallel phenomenon. Food is tempting to a person on a diet in a way that it never is to someone not on a diet, and this constant temptation over time wears one down (Baumeister & Tierney, 2012). Akerlof and Shiller (2015) think it is no accident that Cinnabon shops are often located in airports, where fatigued and discombobulated travelers are lured in by the smell of an 880-calorie Classic Roll. (There is an apocryphal story about a Nobel Prize-winning economist who argued against human rationality by putting up two overheads: One was Shiller’s (1981, 2003) graph showing that stock prices were far too volatile to be derived from rational expectations about dividends; the other was a picture of a Cinnabon).

Channel Factors

Helping people make decisions that are in their own long-term interest has burgeoned as a topic in economics, and economists have taken their work out of the laboratory and into the world. One hot area in economics involves using randomized controlled trials, with interventions designed to help people (usually) in developing countries. In some ways, the economists have taken the birthright of social psychologists in the Lewinian tradition, not only by conducting action research but also by focusing on “channel factors,” small situational features that help people turn good intentions into actual behavior. (Economists use the term “nudges,” rather than channel factors; Thaler & Sunstein, 2008).

In the rich Western World, what could be easier than saving money? We live in a world of historically unparalleled abundance, our pay is automatically deposited in banks, we can have some of this pay diverted to (tax-free) savings and investment accounts, so that we never even see it, and we can arrange to automatically move money from our checking to savings

accounts electronically every month. Yet a large number of us fail to save, with a minority of Americans saving adequately for retirement—or even for the next few months, should an emergency occur (Bhargava & Lown, 2006; U.S. Government Accountability Office, 2015; Huston & Chang, 1997; Kim & Hanna, 2013; Lusardi & Mitchell, 2006; Mitchell & Moore, 1998; cf. Scholz, Seshardi, & Khiatrakun, 2006). (The question, “What could be easier than saving?” is, of course, rhetorical. What could be easier than saving is spending—with credit cards that encourage us to spend more than cash [R. Feinberg, 1986; Prelec & Simester, 2001], credit arrangements that let us make minimal and even interest-only payments, cars and *houses* that can be had for no money down [Financial Crisis Inquiry Commission, 2011], and reverse mortgages and home equity loans that allow us to turn illiquid assets into cash.)

The program Save More Tomorrow was developed by Thaler and Benartzi (2004) to help people in the rich world save more by enrolling them in plans that save an ever larger part of their future income by default. Retirement plans in which enrollment is automatic (unless one actively declines to participate) also have had good success (Beshears, Choi, Laibson, & Madrian, 2006; Madrian & Shea, 2001). The idea is to take some forces that usually prevent employees from saving—tendencies to procrastinate, confusion over choices, feelings of ignorance in financial matters—and have these work to employees’ benefit; inertia thus keeps people *in* savings plans rather than out of them (Benartzi & Thaler, 2007; Iyengar, Huberman, & Jiang, 2004; Thaler & Benartzi, 2004).

However, interventions with a different set of channel factors are needed for the poor of the developing world, who often have no place to put their money (low-balance customers are often unprofitable for banks, so banks discourage them with fees); little access to cheap credit for large purchases (even well-run nonprofit microcredit institutions usually charge at least 20% interest, though informal moneylenders are often available and charge more); are often underinsured against major disruptive events; and are embedded in a network of people who also need money and make claims on friends and family members who have it (this is called by some economists the “relatives tax”; it is the other side—the provider side—of living in a world with an interdependent safety net).

One intervention simply set people up with bank accounts. Rural Kenyan women who were given bank accounts increased their savings (from an average daily balance of about \$5 to \$5.70), increased productive investment in their businesses (from purchasing about \$5 worth of goods for resale to \$8), and increased their spending on food (from about \$1.20 per day to \$1.40) and other expenses (from about 30 cents per day to 40 cents). The authors speculated that putting money in the bank (rather than keeping it in cash) helped women avoid the “relatives tax” and, to a lesser extent, served as a commitment device (preventing them from spending on temptation goods). There was no significant effect on the men, however (Dupas & Robinson, 2013a). In Sri Lanka, sending deposit collectors to make face-to-face home visits increased savings (from about \$7 per month to \$12 per month). It also seemed to create a habit. After 6 months of home visits, experimenters changed to simply having a neighborhood deposit lockbox that was collected on a regular schedule, producing only a small decrease in savings (de Mel, McIntosh, Woodruff, 2013; see also Karlan, Ratan, & Zinman, 2014). Perhaps more intriguingly, the face-to-face collections led participants to work more to increase their income (Callen, de Mel, McIntosh, & Woodruff, 2014). Just having a place to put their money led people to seek more wage employment.

Having a place to put one’s money may also serve another function, allowing one to mentally earmark funds for certain purposes. In a study in Kenya, some respondents were given a lockbox (and key) to save for health expenses. After a year, participants who had the box saved 66% more than those in the control condition, going from about \$4 to \$6 (Dupas & Robinson, 2013b). Though they could open the box at any time and though money is fungible, simply having the box made participants less likely to use the money for daily spending and made them less susceptible to the “relatives tax.” On questionnaires, respondents weakly agreed that they were obligated to give money if someone asked for it and they had cash on hand; however, they strongly disagreed that they were obligated to give money if they had cash in the box. Eighty-one percent said the box made it easier to say “no” to someone outside the household, and 43% said it made it easier to say “no” to a spouse. Mentally earmarking the money legitimated saying “no” for respondents, though it would be interesting to know whether it legitimated a “no” in the eyes of requesters as well. (The parallel earmarking

phenomenon in the United States would be, say, money set aside for children's college education, which is treated as at least somewhat inviolable; see also Morduch & Schneider, 2017).

Mental accounting (Thaler, 1985) and timing seem to be the key to another channel factor implemented in Kenya. Fertilizer makes a farmer's crops much more productive. The problem is that fertilizer is typically bought at the beginning of the growing season—several months after the farmer was paid for his last harvest. At that point, money may be scarce. Simply selling farmers a voucher for fertilizer right after the harvest, when they are flush with cash, increases fertilizer use by two-thirds (from 24 to 38%; Duflo, Kremer, & Robinson, 2011). Of course, the vouchers may be resold at any time, but just buying the voucher was commitment enough to lead the farmers to use fertilizer.

Other interventions are more purely cognitive. These may work by taking into account the “bandwidth tax.” For example, there are standard courses in basic accounting for microentrepreneurs taught by nongovernmental organizations (NGOs). However, an intervention in the Dominican Republic taught entrepreneurs “rules of thumb” (e.g., keep business and personal cash in separate drawers, and do not transfer between them without writing a note) rather than the standard techniques. Such an intervention improved business practices relative to a control group by 6–12 percentage points ($d = 0.25$), whereas the standard treatment did not lead to significant improvement ($d = 0.12$) (Drexler, Fischer, & Schoar, 2014; Karlan et al., 2014).

Some interventions take account of tunneling and work by increasing the cognitive accessibility of important tasks. Thus, simply surveying people (or surveying people more frequently) about health insurance or chlorine treatments for their water increases the likelihood they will subsequently buy insurance or use chlorine (increasing insurance rates from 34 to 40% of respondents and chlorine use from 8 to 24%) (Zwane et al., 2011). Similarly, sending people regular text messages to repay their loans or to save, or giving them a token to keep track of deposits, can sometimes help—though specifics involving what type of message is effective vary across studies (Akbas, Ariely, Robalino & Weber, 2016; Cadena & Schoar, 2011; Karlan et al., 2014; Karlan, McConnell, Mullainathan, & Zinman, 2016; Karlan, Morten & Zinman, 2015; Kast, Meier & Pomeranz, 2012; Zinman & Karlan,

2015). These interventions act like a nudge—or perhaps more like a noodge—in reminding people of important tasks.

In all of these examples, lessons familiar to social psychologists were used to increase commitment, direct attention, reduce temptation, time offers appropriately, and create pathways to turn good intentions into actual behavior. Cognitive-psychological work on heuristics and limits to processing inspired much of the work on the bandwidth tax, mental accounting, and teaching simplified rules of thumb.

Surprises

When economists started closely examining the lives of the poor in the developing world, with, for example, censuses of what they owned or diaries recording daily income and expenses, they found a few surprises. People living on \$1 or \$2 a day do not have a steady cash flow; the \$1 or \$2 per day is an average. This was not surprising. What economists seemed impressed by were how diversified “the portfolios of the poor” were and the ability of even the very poor to save considerable amounts. They also seemed surprised by what the poor in developing countries were spending large portions of their incomes on.

Hedging

An important rule for investing is to diversify one’s holdings. The poor in the developing world seem to have mastered this lesson. Many are what some economists have called “barefoot hedge fund managers.” They have little in an absolute sense, but living with great financial unpredictability and being precariously close to having no money, they are diversified to a degree that might make a Wall Street money manager envious. In daily diary studies of the poor in Bangladesh, India, and South Africa, Collins, Morduch, Rutherford, and Ruthven (2009) found that the poor on average were managing about 10 different types of financial instruments—interest-free loans from relatives, high-interest loans from moneylenders, loans made to other friends or relatives, savings clubs, funeral insurance policies, microfinance loans (primarily in Bangladesh), bank loans (primarily in

South Africa), credit arrangements with shopkeepers, money hidden for themselves or friends (“moneyguarding”), arrangements with others to share wages if they are paid at different times, and so on. “Lower incomes require *more* rather than less active financial management” (Collins et al., 2009, p. 33, emphasis in original). Despite the “triple whammy” of incomes that were small, irregular, and uncertain, none of the households “lived hand to mouth, if we take that phrase to mean that all income is consumed directly and immediately. It is a remarkable finding, and not what might be expected in communities where some scrape by on less than one dollar per day per person” (pp. 31–32). People might be borrowing money on one account while saving on another—much as people in the United States might save instead of paying off high-interest credit card debt—to preserve access to money (see also Morduch & Schneider, 2017).

Furthermore, in proportion to their income, the very poor were able to save up quite a lot for when they needed large lump sums for either opportunities or big expenses. These lump sums averaged about 3 months’ worth of income; and in all three countries, poorer families pulled together amounts that were a larger fraction of their income, as compared to their somewhat wealthier counterparts. Examples of such opportunities might include buying supplies to resell or the chance to buy land. Large expenses might include health emergencies or financial shocks. However, economists seemed surprised at some of the other big expenses.

Festivals and Community

Banerjee & Duflo (2007, p. 146) wrote, “Perhaps more surprisingly, spending on festivals is an important part of the budget for many extremely poor households.” In Udaipur (India), for example, festivals accounted for 10% of the median household’s spending. The expenses for weddings and funerals can be enormous. In one study of rural Indian households, in the year a child was married, 56% of all spending that year was on the wedding (Collins et al., 2009). For South African funerals, ceremonies start a few weeks before the actual funeral and culminate in an event involving 200–600 people. They cost, on average, 7 months of income. Thankfully, most but not all have either formal funeral insurance or belong to informal burial

societies that help defray some of the cost. “Poor families often spend so lavishly on funerals that they skimp on food for months afterward” (Banerjee & Duflo, 2011a).

Weddings, funerals, and festivals are not the “1 percent moments”—moments of weakness that undo the asceticism shown the other 99% of the time—that Akerlof and Shiller (2015) talk about in reference to the developed world. These are the moments for which people plan and sacrifice, demanding months or years of scrimping and saving.

Classifying festivals and life-cycle events as “entertainment,” as some economists do, seems to miss the point of all this. “Part of the reason [these expenses are so large] is probably that they don’t want to lose face” (Banerjee & Duflo, 2011a). But partly such expenditures “are also strategies of aspiration whereby the social-economic standing of [the] whole family can be improved through a ‘good marriage’ ” (Collins et al., 2009, p. 106). Thus, the expense may be an investment. More than that, however, participation in festivals and life-cycle events is probably part of what makes one a member of the community.

To give this a purely economic, “rationalist” interpretation, because the poor rely so heavily on other members of the community to provide what little safety net they have, spending to show that one is a good community member and full participant in the life of the village may have considerable practical benefits. Whether the communal norm to spend a lot on festivals and life-cycle events is good or “rational” for the collective is an open question. However, once the norm is established, it is likely important that individual families show that: they are members in good (or even high) standing, can be trusted to follow communal norms, will not bring shame on those who ally with them, and may be a promising family to marry into. In addition to any practical economic benefits this might bring, participation in such celebrations and observances is important *in itself* to establish that one is a good community member—and hence a person. The African proverb is “a person is a person through other people”; and in such interdependent milieus, one’s personhood and community are inextricably bound. Religious festivals and rites honoring the dead, of course, add a level of spirituality and sanctification on top of this.

Food

Economists were also surprised about how the poor spent on food. “The poor seem to have many choices, and they don’t choose to spend as much as they can on food. Equally remarkable is that even the money that people do spend on food is not spent to maximize the intake of calories or micronutrients. Studies have shown that when very poor people get a chance to spend a little bit more on food, they don’t put everything into getting more calories. Instead, they buy better-tasting, more expensive calories” (Banerjee & Duflo, 2011a, p. 70; cf. Fernald, Gertler, & Hou, 2008; Leroy, Gadsen, Cossio, & Gertler, 2013).

Banerjee and Duflo (2011a, p. 72) approvingly cite Orwell’s (1937) observation about the British poor:

The basis of their diet, therefore, is white bread and margarine, corned beef, sugared tea and potatoes—an appalling diet. Would it not be better if they spent more money on wholesome things like oranges and wholemeal bread or if they even . . . saved on fuel and ate their carrots raw? Yes, it would, but the point is that no ordinary human being is ever going to do such a thing. The ordinary human being would sooner starve than live on brown bread and raw carrots. And the peculiar evil is this, that the less money you have, the less inclined you feel to spend it on wholesome food. A millionaire may enjoy breakfasting off orange juice and Ryvita biscuits; an unemployed man doesn’t. . . . When you are unemployed . . . you don’t want to eat dull wholesome food. You want something a little bit “tasty.” There is always some cheaply pleasant thing to tempt you.

Part of the issue may be a lack of knowledge about the health benefits of various foods. The effects we “ooh and ahh” about as social scientists may be barely perceptible to the naked eye. When researchers gave iron supplements (that help prevent anemia and cost about \$6 a year) to self-employed workers in Indonesia, their earnings for the year went up by \$40. This was a very cost-effective and substantial increase as social science effects go, but was “a gain that may not even have been apparent to [participants], given the many ups and downs of [their] weekly income” (Banerjee & Duflo, 2011a, p. 72). Iodine (in iodized salt) “might make your children smarter, but the difference is not huge, and in most cases you will not find out either way for many years” (p. 72). For those who work for a living, their bodies and brains are their greatest income-producing assets, but that does not mean that effects of micronutrients are any more noticeable.

Similar knowledge issues arise with other surprising purchases. In Banerjee and Duflo's (2007) study of the poor in 15 countries around the world, there was considerable variability, but about one-half of the people living on \$2 per day owned a radio and one-fourth owned a television. About men they visited in rural Morocco, Banerjee and Duflo (2011a, p. 72) wrote, "They struggled to find enough money to give their children a good education. But they each had a television, a parabolic antenna, a DVD player, and a cell phone." Giving people knowledge about what education can do for their children can shift some of this. In terms of bang for the buck, studies in Madagascar (Nguyen, 2008) and the Dominican Republic (Jensen, 2010) indicate that some of the best interventions for improving school achievement simply explain to parents or students the economic returns to education. Such interventions can be done cheaply and may increase years of schooling (about one-third of a year on average) and raise test scores ($d = 0.2$, a decent effect size as such interventions go; Kremer, Brannen, & Glennerster, 2013).

Thus, just giving people information about effects that may be difficult to perceive helps. However, there are also issues of trust and efficacy. Banerjee and Duflo (2011a) warn of a deeper skepticism on the part of the poor. Wariness of authorities seems reasonable in places where corruption is endemic and government programs (e.g., compulsory sterilization in India) have caused deep resentments. This seems hard to ignore in any analysis—even if an intervention program was not from the government or its benefits were visible to the naked eye.

Banerjee and Duflo (2011a, p. 72) wrote:

We often see the world of the poor as a land of missed opportunities and wonder why they don't invest in what would really make their lives better. But the poor may well be more skeptical about supposed opportunities and the possibility of any radical change in their lives. They often behave as if they think that any change that is significant enough to be worth sacrificing for will simply take too long. This could explain why they focus on the here and now, on living their lives as pleasantly as possible and celebrating when occasion demands it.

Channel factors make it easier for poor people to take actions that make their lives marginally better. Contrast this with the developed world, where all of the major steps are built into the system and done for us. In the domain of health spending and practices, clean water comes to us by turning on a tap, sewage is sent away with a flush. Schools force us to become

immunized, employers or governments give many of us the insurance we need, and the food we eat has already been fortified with nutrients and inspected by agencies we trust. The medical professionals we pay to see are usually competent, and their treatments usually do more good than harm (cf. Das, Chowdhury, Hussam, & Banerjee, 2016; Das & Hammer, 2004). And young people's attendance at schools—schools where teachers show up—is mandatory.

Less rationality is demanded of people in the developed world, because rationality is off-loaded onto systems that either force us to be foresighted or (more commonly) just solve problems for us. Even when the work is not entirely done for us, as Banerjee and Duflo (2011b, p. 69) note, people in rich countries “live a life surrounded by invisible nudges. . . . No one is wise, patient, or knowledgeable enough to be fully responsible for making the right decisions for his or her own health” or well-being. Likely this is especially true under conditions of scarcity. The cruel twist is that the burden of making rational decisions falls heaviest on those in the developing world who have the least extra “cognitive bandwidth” to deal with those decisions. (See also below on the “mental space” a middle-class job provides.)

Microfinance, Entrepreneurship, and Employment

Another surprise for many had to do with “microfinance,” which involves giving small loans to people in the developing world, so that they might, say, buy a goat, purchase a sewing machine, buy clothes for resale, or any of the thousands of other projects that might allow entrepreneurs to develop their small businesses (such projects can be seen on www.kiva.org).

On the one hand, there were claims about tremendous gains to be had from unleashing the entrepreneurial energies of the poor. Moreover, microfinance was supposed to be empowering to women. As of 2007, around 70% of microfinance's 155 million customers were women (Armendariz & Morduch, 2010). On the other hand, there were skeptics, who viewed this as another way to put poor people into debt. As Karlan and Appel (2011, p. 9) noted, with microfinance institutions charging interest rates from 10 to 120%, those interest rates were comparable to the rates of

payday lenders that were evoking such anger in the United States. And it did not help when formerly nonprofit organizations went public as for-profit institutions, or when Western hedge funds, lured by double- and triple-digit returns, got into the act (Geisst, 2013).

Results of empirical studies of microfinance, done with reputable microfinance institutions, were likely a surprise to both sides of the debate. Microcredit tended to make modest improvements in people's lives (e.g., allowing them to make some incremental gains in buying durable goods, cushioning themselves against economic shocks, or investing more in their businesses) (Banerjee, 2013; Banerjee, Karlan, & Zinman, 2015). And even with extremely high interest rates, people were paying back their loans. However, the results were not "transformative" (Banerjee & Duflo, 2011b) in the sense of dramatically propelling people upward economically or liberating women. A number of possible outcomes have been examined in microfinance studies; a recent high-profile set of six studies each measured an average of 50 "downstream" consequences (including income, consumption, savings, business profits, trust, women's empowerment, mental health outcomes, etc.). Modest gains were found, though not for want of looking (Banerjee et al., 2015).

The reason microfinance seems not to have lived up to its hype may in part derive from what Banerjee and Duflo (2011b, p. 218) call the "paradox of the poor and their businesses: They are energetic and resourceful and manage to make a lot out of very little. But most of this energy is spent on businesses that are too small and utterly undifferentiated from the many others around them. As a result, their operators have no chance to earn a reasonable living." Being an entrepreneur is hard, and being a successful entrepreneur is even harder. At the low end, every 4 foot by 4 foot store/kiosk by the side of the road looks like every other one (Banerjee & Duflo, 2008). And even somewhat higher up, the economics can be dismal. Instead of golden opportunities, the businesses of the poor "often seem more a way to buy a job" in places where conventional jobs are quite scarce (Banerjee & Duflo, 2011b, p. 226). In some cases, the businesses were a part-time job, but in most cases, businesses were a full-time job, with owners reporting between 40 and 118 working hours (median = 77) per week (Banerjee & Duflo, 2008).

Research on the enterprises of the poor led Banerjee and Duflo to their conclusions about where real economic security is to be found and what it means to be middle class (as opposed to poor). Studying people in the developing world whose spending ranged from \$2 to \$10 per person per day, Banerjee and Duflo (2008, p. 18) wrote that “the key distinction between the middle class and the poor is who they are working for and on what terms.” Rather than being more “entrepreneurial,” members of the middle class are much more likely to be employed in jobs that are relatively secure. With this security, they spend more on their children’s health and education, as well as their own health. In one survey in India, when asked what job they hoped for their children, 80% said a government job; *none* said starting their own business (Banerjee, 2013). “Perhaps the sense of control over the future that one gets from knowing that there will be an income coming in every month—and not just the income itself—is what allows the middle class to focus on building their own careers and those of their children” (Banerjee & Duflo, 2008, p. 26). Consistent with Mullainathan and Shafir’s work (2013) on the cognitive taxes imposed by scarcity and unpredictability, Banerjee and Duflo (2008, p. 26) conclude that “a good job is a steady, well-paid job—a job that allows one the mental space needed to do all those things the middle class does well.”

Summary

Psychologists usually study worlds of abundance. Economists have built their models on assumptions of scarcity. Perhaps, as a consequence, poor people in the developing world look a lot like rational economic actors when it comes to the cool rationality of understanding trade-offs, opportunity costs, and value (as opposed to being influenced by irrelevant context effects). However, scarcity also undermines one’s ability to control the hotter impulses that tempt us to behave in ways that are not in our long-term interest. Lacking the systems and institutions in the developed world that either force or nudge people into good choices, the poor in the developing world face the greatest demands for rational decision making, while lacking the stability and security conducive to long-term thinking.

Despite this, the poor are sophisticated hedgers in a world where incomes are small, uncertain, and irregular. Webs of interdependence often buffer people against the worst (Kraus, Callaghan, & Ondish, [Chapter 27](#), this volume). However, these webs can also prevent people from accumulating enough to escape their precarious economic situations. Interdependence means paying the “relatives tax,” and interdependence means establishing one’s community status—and personhood—through large expenses on festivals, weddings, funerals, and so on. Microfinance—once expected to play a major role in alleviating poverty—appears not to have lived up to early promises, despite the entrepreneurial energies of the poor. Instead, stable employment seems to be key to higher incomes and to the security and “mental space” that allows people to think long term, invest in their children, and make choices that will ultimately improve their health, education, and well-being.

MONEY, TRADE, AND MARKETS: RATIONALIZATION OF INTERPERSONAL RELATIONS AND THE COMPLICATIONS OF INTERMEDIATION

In this chapter’s first section, we described new research on some implications for how scarcity affects people’s hot and cold rationality, noted some ways that poor families “diversify” to hedge against risk, and detailed some of the saving and spending habits that surprised economists. However, it is also useful to step back and consider the basic question of what money is and how it facilitates certain types of relationships and arrangements. On one hand, it “rationalizes” relations between people in Weber’s sense of the term; that is, it makes possible calculable, efficient, methodical, nonarbitrary (“fair”) transactions between people; it facilitates impersonal market exchange; and perhaps as a consequence it can engender a more abstract, rule-bound, universalistic sense of fairness. On the other hand, complex markets have difficulties. To function smoothly, these markets often require go-betweens—“middlemen,” traders—who may be essential but whose work seems superficially to create little value and therefore draws forth

tremendous enmity and prejudice. Complex markets and the niches people create or are forced into hence have the potential to reinforce and amplify ancient hatreds. Complex markets also create intermediating institutions that can alter the way cultural attitudes get translated—or not—into behaviors.

Money Facilitates Impersonal Exchanges

We start with one way that money “rationalizes” relations between people. By reducing everything to a common, quantified metric, money facilitates exchanges between people that are impersonal and calculable.

Walking Away

There is a story about Ernest Seton, a writer and a founder of the Boy Scouts of America. On his 21st birthday, his father presented him a bill for all the expenses incurred during his childhood, including the doctor’s delivery fee for his birth. The bill was \$537.50, and the father figured on 6% interest. According to the story, Seton paid the bill and never spoke to his father again (Atwood, 2008; *etsetoninstitute.org*, 2016; Seton, 1951).

In doing so, Seton (and his father) illustrated one of the primary functions of money. It puts an exact price on something, allows parties settling an exchange to be even with each other, and hence lets them walk away. In this case and others like it, money does not start relationships; money ends relationships. One is further reminded of the misogynist’s quote about prostitution: “Men don’t pay women to have sex. They pay them to leave.”

Money quantifies, attempting to put everything on the same metric. Graeber writes (2014, p. 386) that “the difference between owing someone a favor and owing someone a debt is that the amount of the debt can be precisely calculated. Calculation demands equivalence.” Assuming there is no dominance relationship, parties who have settled their balance with one another can go their separate ways.

One can contrast this with economic exchange in some nonstate societies. Among the Tiv of Nigeria, for example, everyday exchanges often

were designed to *avoid* equivalence. They were designed to be a little off balance, so that relations between people would not end with a single transaction. Thus, if a person paid back a gift, its value would always be a bit more or a bit less than expected, providing some putative reason for the relationship to continue.

Tiv women . . . might spend a good part of the day walking for miles to distant homesteads to return a handful of okra or a tiny bit of change “in an endless circle of gifts to which no one ever handed over the precise value of the object last received”—and in doing so, they were continually creating their society. . . . This sort of neighborliness had to be constantly created and maintained. (Graeber, 2014, p. 105)

It is not that principles of reciprocity did not hold. They did. It is just that every transaction need not be even steven every moment. (See also *osotua* gifts among the Maasai; Cronk, 2007). Relationships would continue and things would even out *over time*. Villages in early modern England worked on a similar principle. There was little gold and silver in circulation, so merchants either made up their own token money or put things on a tab. “In a typical village, the only people likely to pay cash were passing travelers and those considered riff-raff” (Graeber, 2014, p. 327). Everyone else was a debtor to some and creditor to others, and

every six months or year or so, communities would hold a general public “reckoning,” cancelling debts out against each other in a great circle, with only those differences then remaining when all was done being settled by the use of coin or goods. . . . Much like the Tiv women with their gifts of yams and okra, neighbors assumed they ought to be slightly in debt to one another. (Graeber, 2014, pp. 327–328)

This is not to say that gift economies (or early modern economies based on credit) were always based on unadulterated feelings of amity or fellowship (Mauss, 1990; Offer, 1997). One need not “exaggerate the cuddly irrationality of pre-industrial people” as Ridley (2011, p. 134) put it. Gifts serve an insurance function. Principles of food sharing exist, for example, among hunter–gatherers when the likelihood of success is chancy. (As has been observed, “the best place for an Eskimo to store his surplus is in someone else’s stomach,” Wright, 2001, p. 20). Gifts may also be given, accepted, and reciprocated out of fear, to avoid becoming an object of enmity, scorn, or humiliation (Colson, 1974).

Relatedly, gifts are also distributed to demonstrate wealth or status, consolidate power, or—if those who have written about the potlatch are to

be believed—to bury rivals under obligations they could never hope to repay (Bourdieu, 1977; Miller, 1993; Veblen, 1973). In Papua New Guinea, among the Au and Gnau, people are extremely wary of gifts that make them indebted to others. When anthropologists and economists had them play the Ultimatum game—in which one person proposes how to split a pot of money and the other either (1) accepts it or (2) rejects it, in which case both parties get nothing—many offers exceeded 50% of the pot (Henrich et al., 2001). And they were rejected! As Parry (1986) has noted, the idea that there is or should be such a thing as a “free” gift is, in many parts of the world, a strange one.

Regardless of people’s motives for giving, however, there is a clear distinction. In one sort of economy, gifts take place in a context of enduring relationships that are maintained. In the other, money affords the possibility of parties being even steven, able to walk away from one another, and (in principle) able to exchange with anyone they choose. Money thus facilitates the emergence of markets.

Markets, Rules, and Roles

To function efficiently and encourage people to participate in them, markets need rules, which in turn need to be enforced. Legalistic enforcement by an overarching authority is one way this happens, but markets function most smoothly when legalistic enforcement remains salient but in the background. That is, markets function most efficiently when people *trust* one another to abide by principles of fair play.

In recent years, anthropologists and economists have gone to various small-scale societies and conducted economic games, including the Ultimatum game and the Dictator game (in which one person decides how to split a pot of money and the other person must simply accept it). The pot of money can be substantial, in some cases, up to 10 days’ wages. “Fair” offers are those approaching 50% of the pot, and there seem to be three general predictors for whether fair offers are normative in a society. One is whether economic production encourages teamwork and cooperation (e.g., whale hunting among the Lamalera requires teams of people). The more teamwork is required, the fairer offers are. A second predictor is the

presence of what Norenzayan (2015) calls “Big Gods,” that is, whether the group belongs to a religion where a God or Gods watch over the earth and are concerned with what humans do to each other. The Big Gods of world religions require obedience to rules of right and wrong even when no humans are looking. A third predictor is the group’s integration into market economies (sometimes judged qualitatively in terms of how much people engage in market exchange for labor and goods and other times measured quantitatively in terms of percentage of an average household’s calories that are purchased from the market, as opposed to homegrown, fished, or hunted) (Henrich et al., 2005; 2010, p. 1482). The notion is that markets inculcate habits of fair play with strangers.

When the latter two factors are pitted against each other, markets come out first, Gods come out second; that is, market integration produces fair offers somewhat more than participation in a world religion does (Henrich et al., 2010). Again, some extreme groups are interesting to note. As mentioned, in the gift-giving cultures of the Au and Gnao, excessively generous offers were proffered and rejected. On the other end, the Machiguenga of Peru act almost exactly like classical economic theory predicts: In the Ultimatum game (Henrich, 2000), the modal offerer proposes taking the lion’s share of the pot (85%) and recipients of the offer accept! Among the Machiguenga, each family depends solely on itself to produce what it needs and rarely engages in trade with others. In such a system, cooperation with and fairness toward those outside one’s immediate circle usually are neither offered nor expected (see Banfield’s (1958) “amoral familism”; Putnam, 1993; also see Alesina & Guiliano, 2014; Moscona, Nunn, & Robinson, 2017).

To be clear, market economies do not necessarily foster liking, benevolence, charity, or civic duty (Frey, Oberholzer-Gee, & Eichenberger, 1996). What they foster is adherence to an abstract set of guidelines for interacting with strangers, so they can “do business” with each other smoothly and efficiently. They “rationalize” (in Weber’s sense of the term) exchange relations between people.

Trading versus Traders: Outsiders, Intergroup Relations, and the “Stink of Sorcery”

In experimental economic markets (run mostly by Western economists), participants learn the benefits of trade reasonably well. They also seem reasonably good at learning a principle that is often difficult to explain in the abstract. That is, their behavior reflects an understanding of the principle of comparative advantage (we both gain from trade if I do what I do best and you do what you do best—even if you are better than me at doing both).

However, as we’ll also see in the third section of the chapter, whereas some lessons of markets may be easy to learn, others often elude people. Simple trades are easy to understand. Complex markets, on the other hand, have lots of moving pieces.

1. They produce intermediating institutions that affect behaviors in ways that can be hard to predict—and may therefore give rise to perverse attitude–behavior relations.
2. To run smoothly, complex markets also need people to play intermediating roles, but the value of those roles is often intuitively difficult to understand—and hence those roles may inflame ancient, irrational hatreds, as well as create new ones.

Regarding point 2, historically, groups that occupy an outsider status are often forced into various sorts of “middleman” roles or money-handling positions because they have been excluded from guilds and various professions, been forbidden from owning land, or hold a pariah status that prevents people from associating with them for any nonfinancial purpose. Their “middleperson” roles and association with money handling then makes them hated all the more. Thus, certain economic roles reify their outsider status and reinforce others’ enmity toward them.

Simmel and Frisby (2004) noted the association between money handling and marginalized people, citing the Armenians in Turkey, the Parsee and the Chetty in India, the Huguenots in France, and the Quakers in England. All were persecuted and all were merchants, money lenders, or “applied themselves . . . to money acquisition because of their exposed and restricted position” (p. 222).

Trade—rather than production—becomes the specialty of the marginalized.

The role that the stranger plays within a social group directs him from the outset towards relations with the group that are mediated by money. . . . Not only is the trader a stranger, but the stranger is also disposed to become a trader. . . . Dispersed peoples, crowded into more or less closed cultural circles, can hardly put down roots or find a free position in production. They are therefore dependent on intermediate trade which is much more elastic than primary production. (Simmel & Frisby, 2004, pp. 224–225)

The position of a “middleperson” minority is a no-win position. Primary producers who sell their goods to the middleperson for amount X may feel cheated when the middleperson turns around and sells them for $1.2X$. The end buyer who has to pay $1.2X$ for goods that the middleperson bought for only X may also feel cheated. The surplus goes to the middleperson simply for being the intermediary. The risks taken by the middleperson (who may not sell the inventory and who may have to sell on credit to buyers) and the services provided by him or her (in distributing, selling, and catering to customers; transferring knowledge of the market back to producers [Atkin, Khandelwal, & Osman, 2017]; acting as an intermediary between peoples who will not deal with each other; etc.) are invisible. As Sowell (1996, p. 32, citing Hayek, 1988) notes, “To make money from the mere transference of a physically unchanged product from the producer to the consumer ‘stinks of sorcery’ to the economically uninitiated.” Despite performing many necessary functions in a complex market, middlepersons historically have often been considered parasitic. Medieval Catholicism—in comparison to Islam, a religion founded by a merchant—was much harsher toward markets, and toward middlepersons in particular, arguing that the latter’s profit was justified only as “payment for his labor (i.e., in transporting goods to wherever they were needed)” (Graeber, 2014, p. 290). The logic of trading may be relatively easy for people to understand, the role of traders has been much harder for people to recognize.

Most middlepersons start small as, say, peddlers or street vendors. Most remain small, working long hours on thin profit margins, trying to make money on volume rather than markup. Some are successful, and the salience of the success stories—from middleperson groups such as Jews; Ibos in Nigeria; Tamils in Sri Lanka; Indians and Pakistanis in East Africa; Greeks, Lebanese, and Armenians in the Ottoman Empire; and Chinese in Southeast

Asia—has often provoked much resentment. That these groups are vulnerable to having their wealth seized by the state or by their neighbors—because they are a minority, are despised, and often have to hold their wealth in an easily steal-able form (say, cash rather than land)—does not help. Their outsider status constrains them to work in certain positions, those positions further the majority group’s feelings of enmity, and the group’s vulnerability makes them easy targets for exploitation.

Successful outsiders in particular have historically been targets of violence, with either mob violence or state slaughter of, for example, Armenians, Ibos, Jews, and so on (Sowell, 2005). Brustein and King (2004) provide an interesting case study. They contrast Romania with its southern neighbor Bulgaria. In 19th-century Romania, Jews played a middleperson role as agents between the landed elite and peasants. In the 20th century, they were overrepresented in the professions, journalism, and the financial sector, as well as leftist politics. In Bulgaria, Jews were not particularly successful and played little role in leftist politics. When World War II came, actions by the Bulgarian government and citizens saved almost all Bulgarian Jews from the Nazis. In Romania, where Jews had been middlepersons and later successful professionals, there was strong anti-Semitism before World War II; and when the war came, “even the [Nazi] SS were taken aback” by the brutality of what they saw, with the SS sometimes intervening to save Jews so they could be killed “in a civilized way” (Arendt, 1963, p. 190).

Lending

If the middleperson role has historically drawn resentment, so has the role of the moneylender. They too have been seen as parasitic or predatory. In the contemporary United States, the term “predatory lending” is reserved for those who take advantage of people’s ignorance or difficult circumstances, or charge an interest rate deemed too high. However, historically, and in the contemporary Muslim world, any sort of lending at interest was deemed predatory.

At issue here is a basic conception of what a loan is or what it should be—an act of charity or an act of business/mutual gain. It is worth going through the history, because it reveals something about the way various

cultures have conceptualized money and how it should function in ingroup relationships. Furthermore, studying the history of cultural attitudes about lending and borrowing provides a useful lesson about the way complex markets—and the intermediating institutions they produce—can create perverse attitude–behavior relations. More particularly, it shows how antidebt attitudes can help create institutions that subsequently produce heavily indebted societies.

Interest

Many societies regard lending at interest with profound ambivalence. As Graeber (2014) notes, two moral injunctions hold across many cultures: “(1) paying back money one has borrowed is a simple matter of morality and (2) anyone in the habit of lending money is evil” (p. 9). However, a concern with usury has been a matter of special concern among the Abrahamic religions (Judaism, Christianity, Islam).

Among major religions that developed in South and East Asia (Buddhism, Hinduism, Confucianism), none objected to charging interest, though Hinduism did place limits on it (Gelpi and Julien-Labruyere, 2000; Graeber, 2014; Houkes, 2004). And whereas Aristotle, for example, argued against the practice of usury because money was “sterile” and thus could not reproduce (Houkes, 2004), in the ancient Near East (before the Abrahamic religions), there was no such conception. “These societies regarded inanimate matter as alive, like plants, animals and people, and capable of reproducing itself. Hence, if you lent ‘food money’ or monetary tokens of any kind, it was legitimate to charge interest. Food money in the shape of olives, dates, seeds, or animals was lent out as early as c. 5000 B.C., if not earlier” (Johnson, 1987, p. 172).

The Jews were likely the region’s first group to object to charging interest. Jewish prohibitions on charging interest “were in sharp contrast to all known legislation of the Near East” (Houkes, 2004, p. 86). In Judaism, it was forbidden for a Jewish person to charge interest to another Jewish person, though one could charge interest on loans to non-Jews. The prohibition on charging interest to fellow Jews “seems to have been designed to protect and keep together a poor community whose chief aim was collective survival.

Lending therefore came under philanthropy” (Johnson, 1987, p. 173). Judaism still considers gifts *or interest-free loans* that make a person self-sufficient to be the highest form of giving. It was a commandment to give such loans to a brother, but not to an outsider.

Later, it was “Medieval Christianity, aspiring to universalism . . . [that] proposed to transcend the morality of clan by joining the ‘other’ to the ‘brother’ ” (Nelson, 1969, p. xxiii). The prohibition on interest is not found in the New Testament but was developed by the Church later. Again, the conception was that the loan was an act of charity, and this charity was due to everyone (Houkes, 2004).

Jews could legally charge interest to Gentiles, so they became a source of loans, but by the 1100s “most Jewish moneylenders had long since been displaced by the Lombards (from Northern Italy) and Cahorsins (from the French town of Cahors)—who established themselves across Western Europe and became notorious rural usurers” (Graeber, 2014, p. 289).

There were, in fact, always ways around usury bans—just as there are in Islamic finance today. For example: different prices could be charged for cash and credit; a sale could take the form of a joint business venture, from which it was acceptable to profit; loans could incur “fees” or “commissions,” and so on (Graeber, 2014; Homer & Sylla, 2005; Robinson & Nugent, 1935; Wilson & Kim, 2015). One has the impression that the ban on interest was a bit like bans on premarital sex or masturbation. The bans didn’t stop the behavior, but people weren’t supposed to flaunt it or feel good about it (for a heterodox view that usury laws were highly effective, see Tan, 2002).

It was not until the Protestant Reformation that interest (though not excessive interest) became legitimate. In fact, interest was “the dominant financial theme” in the writings of Protestant reformers (Jones, 2004, p. 3). Of all people, it was John Calvin who was crucial for making interest respectable. One might naively have thought Calvin would be against charging interest, because it was a way of earning money without doing anything and therefore a reward for sloth. Action, not indolence, was at the root of Protestant asceticism and its famous work ethic (Weber, 1905/1958).

However, there were two crucial and related issues for Protestant reformers according to scholars. One was the framing of interest as a matter of fairness, moving the loan from the domain of charity to the domain of business (or at least mutual advantage): If one rents out a field for money,

why couldn't one also rent out money for money? (Wykes, 2003). The second issue concerned changing ideas about the relations between people. Nelson (1969, p. 73) has argued that a key move was going from the Universal Brotherhood of Catholicism to the "Universal Otherhood" of Protestantism, "where all became equally 'brothers' in being equally 'others'" (see also Sanchez-Burks, 2002; Uhlmann & Sanchez-Burks, 2014; Levine, Harrington, & Uhlmann, [Chapter 23](#), this volume). As a general matter, "Universal Otherhood" was one way Calvinism was highly compatible with the ideology of a market economy (Weber, 1905/1958), with the "otherhood" suited to competition and impersonal market exchange and the "universalism" suited to commitment to abstract rules of fair play widely applied (Inglehart, 2001; Lipset & Lenz, 2001). In the specific case of lenders and debtors, "Universal otherhood" legitimated the practice of lending at interest, though at a rate neither excessive nor exploitative.

Catholicism placed the primary stigma on the lender (the usurer). Protestantism moved a good portion of the stigma from the lender to the debtor. Of course, debtors who could not pay back were stigmatized everywhere. But Protestantism went further than merely stigmatizing failure to repay. As economist Benjamin Friedman (2014, p. 61) wrote, "by the beginning of the nineteenth century evangelical Protestants had mostly come to regard borrowing as sinful, even when the debt was serviced and repaid on a timely basis." In England, paying in cash was seen as the moral thing to do (Graeber, 2014; also see Keynes, 1936, on the valorization of saving). And the stigma against borrowing covered not just people but governments, "whose Original Sin was the National Debt" (Friedman, 2014, p. 61, quoting Roseveare).

In Catholic countries of Europe, the stigma on interest held on for a few hundred years before partially giving way in the 19th century (Houkes, 2004). In 1950, Pope Pius XII officially asserted that bankers "earn their livelihood honestly" (Homer & Sylla, 2005, p. 78). Over the past two centuries in Europe, prohibitions against interest have been removed, but controls were instituted and usury rates capped in various countries. Such caps have gone on and off, but the caps seem to have been more frequent in Catholic countries, as opposed to Protestant ones, where caps either did not exist or were ineffectual (Harrison, 1899; Reifner, Kiesilainen, Huls, & Springeneer, 2003; Reifner, Clerc-Renaud, & Knobloch, 2010).

Even today, when it comes to debt collection, Catholic countries are relatively more friendly toward debtors, whereas Protestant countries are relatively more friendly toward creditors (see, e.g., rankings by Wood, 1995; Djankov, McLeish, & Shleifer, 2007).¹ And as an independent test of the hypothesis, our own data show similar effects within the United States: States with a greater proportion of Protestants scored higher on procreeitor/antidebtor measures across a number of indicators (Cohen, 2017).

Culture, Institutions, and the Potential for Perverse Attitude–Behavior Relationships

Given Protestantism’s historical tendency to stigmatize borrowing, one might expect to find that household debt loads are quite low in Protestant countries. This expectation, however, would be wrong. Over the last 30 years, countries with the highest levels of household debt have generally been English-speaking (United States, Canada, United Kingdom, New Zealand, Australia) or Nordic (Denmark, Finland, Norway, Sweden), rather than Catholic (Spain, France, Italy, Portugal, Austria, Belgium) (Organization for Economic Cooperation and Development, 2006; Cecchetti, Mohanty, & Zampolli, 2011; Girouard, Kennedy, & Andre, 2007).

Why this is the case is quite interesting, because it seems likely that the attitudes and behaviors *are* causally related, but in a way that inverts the usual relationship. The presence of intermediary institutions seems to be the key. As noted, Protestantism shifted the stigma from the lender to the debtor and, as a consequence, it seems to have built legal rules, institutions, and practices that are procreeitor, removing some debtors’ rights and giving creditors more protection and more efficient recovery should their loans turn sour. All else being equal, greater protections for creditors make them more likely to lend (regarding increased lending and longer maturities in places with stronger creditor rights, see Bianco, Jappelli, & Pagano, 2005; La Porta, Lopez-De-Silanes, Shleifer, & Vishny, 1997; Levine, Loayza, & Beck, 2000; Pagano, 2001; Pence, 2006; Qian & Strahan, 2007).²

Thus, antidebtor attitudes (historically more prevalent in Protestant countries) turned into procreeitor laws and practices, creating institutions

that opened up the spigot of money to be loaned. Opening up cheap and abundant supplies of credit in turn seems to have led to high levels of borrowing (and hence indebtedness) in primarily Protestant countries. Again, the link is not from attitudes → behavior but from attitudes → institutions → behavior, with protections for lenders inverting the usual attitude–behavior relation.

Obviously, having access to credit does not cause everyone to max out, but it does increase the temptations. Those with no access to credit are (in nonemergency situations) far less likely to get into trouble borrowing—though in emergency situations, they may be at the mercy of payday lenders or loansharks.³

An “Exception”

There is a salient “exception” to the pattern of overindebtedness described earlier. As private householders, people in Protestant countries may be more in debt than their peers in Catholic countries. However, when it comes to public debt, it is the other way around. Governments in Catholic countries are far more indebted than those in Protestant countries, and the “religious war”—as France’s Economic Minister and later President Emmanuel Macron called it—between governments arguing for austerity (vs. bailouts) has pitted thrifty Calvinists against free-spending Catholics (Donahue, 2015).

Why the reversal when it comes to government debt? There are likely many reasons. However, two of them relate to issues we discussed earlier. Debt crises seem to be precipitated not by long-term debt but by short-term debt that won’t roll over (Reinhart & Rogoff, 2009). Thus, the crisis situations facing countries teetering on the edge are less analogous to a person with lots of student loans and more analogous to a person facing a payday lender who won’t roll the debt over. Second, when it comes to private lending, credit may be constrained in Catholic countries because lenders are less likely to make loans. However, in Europe, until recently, governments printed their own money. Thus, a constraint—the supply of credit denominated in one’s own currency—is considerably loosened; perhaps, as a

result, the public debt of Catholic countries exceeds that of their Protestant counterparts.

A government in debt trouble can default or reschedule its debts, or it can, in effect, repudiate the debt through debasing the currency. In terms of default or rescheduling, the pattern has been reasonably consistent over the last 200 years. Since 1800, no primarily European Protestant country (United States, Canada, United Kingdom, Australia, New Zealand, Denmark, Norway, Sweden, Finland) has defaulted or rescheduled its debt. This contrasts with the 67 defaults or reschedulings for the other countries of Europe (data from Reinhart & Rogoff, 2009).

The pattern for debasing the currency—what Reinhart & Rogoff (2009, p. 174) call “an ‘Old World’ favorite”—is similar, though not as extreme. In the past, governments physically debased the currency—shaving down coins or mixing in cheaper metals—and paid back their debts with cheaper money. Now that fiat money (which has no intrinsic value) is used, “modern currency presses are just a more technologically advanced and efficient approach to achieving the same end” (Reinhart & Rogoff, 2009, p. 174). Over the years, primarily European Protestant countries have done less of this debt repudiation through debasement, while primarily European Catholic (or Orthodox) countries such as Austria, Belgium, Greece, Hungary, Italy, Poland, and Russia each spent over 10% of the past 200 years with inflation rates above 20%. (One could also look at peak inflation rates, but one would have to do something with outliers such as Austria, Germany, Greece, Poland, Russia, or record-holding Hungary, which in 1946 had an annualized inflation rate of 963,000,000,000,000,000,000,000%.)

Overall, the “exception” of government overindebtedness in Catholic countries may lend credence to the causal mechanism for private debt described earlier. For private debt, the stigmatization of borrowers created procreditor institutions that effectively increased the supply of credit, leading, ironically, to higher levels of indebtedness among Protestant citizens. When it comes to public debt, countries print their own money. Hence, one of the constraining factors (the supply of money) is loosened, and Protestant versus Catholic (and Orthodox) patterns of debt thus reverse.

Summary

Money and the market exchanges it facilitates are a way of “rationalizing” relations between people, allowing for elements of calculability, efficiency, and interchangeability. Its ability to facilitate trade, as well as encourage adherence to rules of “fair play” within the market, seems demonstrated in research on small-scale societies. The principles also apply as societies and markets scale up. However, complex economies have lots of moving parts, some of which draw resentments or “stink of sorcery” (in Hayek’s [1988] words) and inflame ancient, irrational prejudices against outgroups or create new ones. Complex markets also lead to the development of institutions—financial intermediaries (banks), credit bureaus, and crucially, the laws of state and nonstate organizations that protect them. The creation of these institutions reflects popular sentiment (thus, antidebtor countries create rules and practices favoring the lenders). However, the presence of these institutions can in turn affect behaviors in nonobvious ways, for example, when historically antidebtor nations make lenders so safe that credit expands widely enough for the population to take on comparatively high levels of private debt.

Money and markets “rationalize” in the sense of making economic exchange more rule-bound and efficient. Yet the workings of complex markets are not so easy to understand, reinforcing prejudices against groups that assume intermediating roles in the market and creating intermediating institutions that effectively invert attitude–behavior relations.

MARKETS, CRASHES, AND BUBBLES

Economist Vernon Smith (2013) won the Nobel Prize for his work on experimental markets. His early experiments resembled real-life markets for “nondurable goods and services,” such as hamburgers or haircuts. Goods could not be retraded, and markets worked efficiently, quickly settling on prices and maximizing gains from specialization and trade.

A few decades later (in the 1980s), V. Smith focused his experimental markets on assets that were “durable” and could be bought and sold, such as houses, stocks, or bonds. These markets incited speculation and often produced bubbles and crashes. Even when participants knew exactly what assets were “worth” in terms of pay from the experimenter, prices still rose

far above the asset's value, then came crashing down (Noussair, 2017; Porter & Smith, 1995).

However, “until the Great Recession [2007 and on],” V. Smith (2013) later wrote, “I did not fully appreciate the important differences in these two kinds of experimental markets—the durable and the nondurable, or the house and the hamburger. What is now clear is that although markets work miracles in the [nondurable] case, they can be ugly and painfully unstable in the [asset case].” The latter markets are susceptible to speculative frenzies and panicked sales—the famous twins of Greed and Fear that can lead to bubbles and crashes.

People often debate whether “the market” is rational or irrational. But there is no “*The Market*.” There are *lots* of markets, spread out over time, space, and function; and treating them all as “the market” may be one reason for some of the contradictions we highlight below. In the next section, we explore the role of culture in the making of asset bubbles and crashes.

The Role of Culture in Bubbles and Crashes

Debt crises provide an interesting example of market behavior, because they illustrate how much the system rests on collective faith and how ephemeral that faith can be. As noted, according to Reinhart and Rogoff (2009), it is not long-term debt that causes crises. It is short-term debt that is continually renewed by creditors who have faith—until they don't.

In this way, debt crises are much like other crises, in which a collective understanding holds, then suddenly changes. Various writers have outlined the stages by which bubbles form and pop. This is usually done in hindsight, because, as has been observed, no one knows it's a bubble until it has popped. Of course, this isn't always true. Some people see the train wreck coming. But sometimes there is little they can do about it. They can “short” stocks, borrowing shares and selling them with the promise that they will repurchase the shares later at (they hope) a lower price. In theory, “shorting” should allow individuals to make a killing betting against the market, and at the aggregate level, shorting should prevent bubbles from forming, if there are enough level heads in the market. However, shorting is a risky strategy

for investors, because losses are potentially unlimited, since there is no upper bound on how high speculation can drive a stock price. The market may eventually come back to a rational price, but as Keynes (1936) noted, markets can stay irrational longer than most investors can stay solvent.

With the benefit of hindsight, though, some have sketched out the life cycle of a bubble this way: First, some change (often a technological or financial engineering change) emerges that people begin to regard as somehow revolutionary (Reinhart & Rogoff, 2009; V. Smith, 2008). A narrative—and market enthusiasm—builds and gains credence (Akerlof & Shiller, 2011; Shiller, 2015). But at some point, the narrative itself may become irrelevant, and people start hoping to ride off market enthusiasm, trying to make money by “flipping” houses (in the recent housing crisis) or buying and selling tulip bulbs (in the Dutch tulip bulb bubble) or Internet stocks (in the dot-com bubble). At this latter stage, buyers may be operating on the “greater fool” theory—that there is always going to be a fool greater than you to whom you can sell the asset (Scheinkman & Xiong, 2003). And it works. Until it doesn’t.

Bubbles and panics are not rare events. Depending on the time frame and how one does the calculations, extreme events happen tens to hundreds of times more often than one would expect if one were predicting market movements based on a normal curve (Kaplan, 2009; Nordhaus, 2011). For example, Ferguson (2008, p. 165) calculates that “an annual drop of 10% or more would happen only once every 500 years, whereas on the Dow Jones, it has happened about once every five years.” Peak-to-trough declines of 20% or more in the stock market should be shockingly rare events, yet they happen in the United States (historically the best performing stock market in the world) on average every 10 years (Kaplan, 2009).

For those studying culture, there are at least two interesting phenomena here. The first is the construction of the collective narrative about why the world has changed, and why this time is different. The second, and more relevant to how people think about money, is the lay understanding of how markets work and the underlying contradiction that lies at the center of many Americans’ beliefs.

Narratives about Change

The construction of the narrative of how the world has changed is seemingly straightforward. As of this writing, the two most recent bubbles were the dot-com bubble and the housing bubble. The idea behind the dot-com bubble was that the Internet was going to set off a huge productivity boom—as some observed, evidence for this showed up everywhere but in the data. The housing bubble was driven on the financial side by “innovations” or “financial creativity” (Financial Crisis Inquiry Commission, 2011, p. 6) in securitizing mortgages (allowing mortgages to be bundled, then sliced and diced into “safe” investments⁴). From the consumer’s side, the housing bubble was driven by the wisdom that “they aren’t making land anymore.” (As Blodget (2008) noted, were they ever making more land?) The expression “safe as houses”—an expression coined by sailors trying to reassure nervous passengers on boat rides—came to imply a truism that housing was always a safe bet (Akerlof & Shiller, 2011).

Similar stories about how things had changed had been told before: In the 1970s, excess lending by Western banks to developing countries was deemed acceptable, because these were bank loans, not debts financed by bonds. (That ended with bubbles bursting and defaults in over a dozen emerging markets in the 1980s). A little later, excess lending was okay, because these were debts financed by bonds, not by bank loans. (That ended with debt crises in Latin America in the 1990s and 2000s). And so on—always with an explanation for why “this time is different” (Reinhart & Rogoff, 2009, pp. 17–20; Blodget, 2008).

Ironically, the most recent crashes were brought about by financial innovations that, on the face of it, seemed like they would create more safety. The mass securitization of mortgages should make the secondary market for mortgages safer, because bundling many mortgages together should make default risks more predictable. The presence of credit default swaps allows companies to buy insurance against other loans defaulting.

The problem in securitization is that if no one looks at the underlying assets being securitized, garbage assets can get hidden. With credit default swaps, one party is laying off risk by buying insurance against a default, while another party is taking on risk by betting that a default will not happen. The agreements are clear enough in simple cases, and the ability to off-load risk (as in, say, people buying insurance or farmers locking in sale prices in advance with futures contracts) is extremely useful. However, the

modern economy has gotten so complex and interconnected (through institutions “too big to fail”), and the financial instruments so difficult to understand and assess, that investors and companies (including those “too big to fail”) entered into risks without actually being able to calculate those risks. All of that is fine—until it isn’t. Then the complicated contracts and tangled risks they created became “financial weapons of mass destruction,” as Warren Buffet called them.

So why was the danger of a housing bubble—and all the complex derivative contracts layered on top of it—not recognized by enough people? Why was the tech bubble not recognized? Why will the next bubble not be recognized?

Part of the answer seems understandable in terms of informational influence (Sherif, 1936). The claims of “this time is different” seem sensible at the time, because everybody else (including some very smart people) seems to believe them and credible-sounding arguments have been amassed. Historical examples testify to how easily people are persuaded that “this time is different.” And cognitive psychology experiments on the difficulties of analogical transfer testify to people’s inability to see how this situation is similar to previous ones (Gick & Holyoak, 1983; Holyoak & Koh, 1987; Novick, 1988). In the laboratory, speculative bubbles occur in experimental markets not only with undergraduates but also with experienced, knowledgeable people: small-business persons, midlevel executives, and professional stock traders (Porter & Smith, 2003). Repeated experience playing in these laboratory experiments can reduce bubbles. However, just changing the parameters (without changing the basic rules) is enough to rekindle bubbles even with experienced participants (Hussam, Porter, & Smith, 2008). The problem is that the apocryphal Mark Twain quote was right: “History does not repeat itself, but it does rhyme.” And, depending on a number of factors, people can face some serious cognitive limitations in seeing why one situation is like another (Gentner, Loewenstein, & Thompson, 2003; Kotovsky, Hayes, & Simon, 1985; Reeves & Weisberg, 1994).

However, a purely informational account of how bubbles emerge or one that stresses purely cognitive limitations likely misses some important elements—including the strong affect created by the Fear Of Missing Out, a feeling that is known well enough that it often just goes by the acronym

“FOMO” (see also Andrade, Odean, & Lin, 2016; Lee & Andrade, 2015). The fear of being left behind seems to be more powerful than the risk that we all go down together. Furthermore, a purely informational account misses some of the institutional pressures driving conformity. Money managers have to explain to their clients and bosses why they are not putting money in the places that are making all the other people rich. They don’t have to explain—and have less to lose—when they do the same thing everyone else is doing (as in the dated expression “No one ever got fired for buying IBM”).

Note that informational and normative influence can nullify the benefits of markets as aggregators of information. Part of the reason why markets are seen as all-knowing is that they aggregate the “wisdom of the crowd”—with enough independent agents, errors (random deviations from the true value) cancel out and the signal (the “true value”) comes through. Markets can tolerate *a lot* of noise, as long as errors offset each other. However, when normative or informational cascades influence waves of people, agents are no longer independent, mistakes may no longer cancel out, and prices may abruptly move away from “true” values.

And then there are more nefarious explanations for why speculative frenzies are not offset by level-headed thinking. These go by what economists call “principal-agent” problems, in which principals act through intermediary agents, who face incentives different than those of the principals. Thus, fund managers (agents) take 20% of the gains but none of the losses (borne by the investors [the principals]). Employees (agents) may take huge risks with money belonging to their company (the principal), because potential rewards to the employee (millions of dollars in bonuses) are more important to them than potential losses to the company. Or a company (as the agent) may sell hugely risky assets to clients (principals), because the company is trying to unload its own bad bets, or because rewards for the company (millions of dollars in commissions) are more important to them than clients’ potential losses. Needless to say, principal-agent problems also nullify markets’ ability to find “true value.”

Narratives about Markets

The collective narrative about markets and easy money (especially during a bubble) is interesting, because it reveals a profound ambivalence or even a contradiction in American beliefs about the efficiency or inefficiency of markets. If members of the lay public are confused on this point, they can take heart that the matter is not completely settled in professional circles either. An example of professional collective sensemaking (or perhaps mythmaking) can be found in the story of what happened when Maurice Kendall (of Kendall's tau) examined stock market returns. Eager to use newfound computer power, Kendall (1953) analyzed data on stock market returns and found they were essentially unpredictable, moved more by "animal spirits" than by any comprehensible pattern. The results were distressing for economists, who were shocked to find that the market moved in irrational, unpredictable ways (Bodie, Kane, & Marcus, 2014). That reaction did not last. At some point, economists decided that unpredictable stock movements were the ultimate sign of the market's rationality. If all the information known at a given moment is incorporated into the price, anything qualifying as "news" (i.e., anything that was unforeseen) could only lead to unpredictable movements in price. (If a stock moved in some predictable way, it would indicate that some information had *not* already been incorporated into the price; hence, only *inefficient* markets would be predictable. For a brief history of how random movement came over time to seem like a "self-evident" form of efficiency, rationality, see Dimson & Mussavian, 1998, p. 91.)

The professional struggle over what "unpredictability" means and what "efficiency" and "rationality" imply continues today. The 2013 Nobel Prize in Economics was awarded to three economists for their work on asset pricing—one of whom (Eugene Fama) is famous for his vigorous defense of an efficient market hypothesis and another (Robert Shiller) is famous for his work vigorously challenging such a hypothesis, calling it "one of the most remarkable errors in the history of economic thought" (1984, p. 459).

Disagreements within the profession are reflected in the paradoxical attitudes that Americans hold toward markets. Americans, in general, tend to be pro-free market (at least compared to other countries). They tend to believe that markets are fair and that they are efficient. Regarding efficiency, however, they—like pre-Kendall economists—tend to have a very different understanding of what "efficiency" means. They believe it is possible to beat

the market. In Sapienza and Zingales's (2013) survey, one of the greatest discrepancies between beliefs of professional economists and those of laypeople was found on the item asking whether it is hard to predict stock prices. Of approximately 40 economists surveyed, 100% agreed it was hard to do so. Of the lay public, only half as many did (55%). Strangely, when told that "nearly all economic experts agree" that it is hard to pick winning stocks, people seemed to dig their heels in, and agreement that it is difficult to predict prices dropped to 42%.

It should be noted that with more people choosing to invest in mutual funds, investors may be acknowledging that they personally may not be able to outpick everyone else. However, as of this writing, most of these mutual funds (85%) were actively managed funds charging fees between 1 and 2%, as opposed to passive index funds that mimicked the market (or segments of it) and charged much lower fees (Bodie et al., 2014). Thus, people may be less likely to think they can outsmart the market by picking the best stocks, but they still seem to think they can outsmart the market by picking the best stockpickers and will pay to do so. While there is some evidence for a very small number of superstar stockpickers, the vast majority of highly paid money managers do not consistently outperform the market enough to cover their fees. That one can beat the market by picking the stockpickers seems about as unlikely as one beating the market by picking the stocks (Bodie et al., 2014).

If Americans indeed thought markets were predictable in principle—and predictable by them personally—one might expect to see them investing based on past trends. The most straightforward way to do so is simply to extrapolate: Stocks that have gone up will continue to go up, and stocks that have gone down will continue to go down. And to the chagrin of those who believe in a strong version of the efficient market thesis that stock movements will be random (Fama & Thaler, 2016), they do—at least for a little while before reversing.

It is not completely clear why this "momentum" occurs, but some have attributed it to investor overconfidence—more particularly, "peer-comparison overconfidence," or the belief that one is better than one's peers on some dimension (Chui, Titman, & Wei, 2010; Daniel, Hirshleifer, & Subrahmanyam, 1998; Yates, Lee, & Shinotsuka, 1996). If informed investors see themselves as better able to predict the future than their peers, they are

likely to overreact to good news about a company/industry/fund (pushing prices up further by buying) and overreact to bad news (pushing prices down further by selling) (Daniel et al., 1998).

Indeed, Chui et al. (2010) showed that stock momentum is greater in the United States than in Asia. This is consistent with Americans being likely to show greater self-enhancement biases, believing they are better than other investors and smart enough to beat the market (see also Griffin, Ji, & Martin, 2003).⁵ Later, Chui and colleagues (2010) expanded their analyses to 41 markets around the world, using individualism scores from Hofstede (2001) to proxy for tendencies to think one's abilities are better than one's peers' abilities. They showed that individualism did predict momentum, even with a range of controls, and even if samples from Asia were excluded. Furthermore, individualism predicted trading volume and volatility—two indicators also hypothesized to derive from investors' overconfidence in their own abilities. Believing in their own competence over that of their peers (to a degree in no way justified by the evidence), individualists are more willing to trade stocks and will do so more frequently (to the detriment of their own profits) (Barber & Odean, 2000, 2001; French, 2008; Gervais & Odean, 2001; Scheinkman & Xiong, 2003).

None of this is to say that individualism makes a place particularly prone to major booms and busts. Asset crises, banking crises, and defaults seem to be relatively common throughout the world (Calomiris & Haber, 2014; Reinhart & Rogoff, 2009). It is just to say that some of the features of individualism that should protect against bubbles and irrational valuations—protections against corruption (Jensen, 2005; Li, Triandis, & Yu, 2006; Licht, Goldschmidt, & Schwarz, 2005; Mazar & Aggarwal, 2011), generalized trust that leads to greater participation in stock markets (Guiso, Sapienza, & Zingales, 2008), a contrarian attitude that makes one less likely to conform (Beckmann, Menkhoff, & Suto, 2008; Eun, Wang, & Xiao, 2015)—are offset by individualism's fostering of overconfidence in one's ability to analyze trends, extrapolate linearly, and outsmart the market. In Chui and colleagues' (2010) data on momentum, overconfidence in fact more than offsets these other forces.

Compared to their European peers, many contemporary Americans have a profound faith in "The Market." They think markets, as opposed to central planning, produce the most efficient outcomes.⁶ They trust the self-

interest rather than the benevolence of the butcher, brewer, and baker to provide their dinner and believe the invisible hand promotes the public good (A. Smith, 1776). And Americans believe “The Market” delivers fair outcomes (that people get what they deserve, and that redistributions are unfair and mess with appropriate incentives). Yet despite believing that markets have this Solomonic wisdom, they also believe that they can beat them.

Again, in times of normal market behavior, this costs them in terms of fees, overtrading, and so on. In times of cheap credit, narratives about innovation, and periods of speculative excess, this costs them in terms of creating bubbles that subsequently pop. Believing in the wisdom of markets, Americans benefit in ways Adam Smith (1776) described. Believing in their own wisdom, Americans—and people elsewhere—also create speculative bubbles and busts in ways Vernon Smith (2013) described.

The \$20 Bill

There is an old joke about an economist walking down the street and stepping over a \$20 bill. When his friend asked why, the economist replied that the bill must be a fake, because if it had been a real \$20 bill, someone would have already picked it up. Strong forms of efficient market theories have this paradox. Markets are supposedly efficient because they aggregate the wisdom of many different players. Yet, if everyone truly believed in an efficient market, no one would trade, and there would be no new information to integrate. Few people (outside of economics departments) actually believe in the strongest form of the efficient market hypothesis, however, and in general, those in individualistic cultures seem reluctant to abandon their overconfidence.

Summary

Sociocultural factors play an important role in the bubbles and crashes that are a routine part of asset markets. Bubbles develop because of cultural narratives about some revolutionary technological or financial change that makes people believe “this time is different.” In the recent housing crash, the

revolutionary change involved financial innovations that were supposed to make markets less risky, but instead became so tangled, complicated, and opaque that few people could actually understand them until the losses sent them reeling.

The belief that there is easy money to be made in a bubble—or in any market—reveals a contradiction at the center of many Americans’ faith in the market. They have faith in the Solomonic wisdom of markets, yet at the same time believe they are smart enough to beat those markets, buying and selling too much for their own good. Across countries, individualism generally is correlated with trading volume, volatility, and the market anomaly of “momentum,” consistent with individualists’ tendencies toward overconfidence. (Moreover, even when people concede that they personally cannot pick the best stocks, their overconfidence merely gets transferred to the next level up, in the belief that they personally can pick the best stockpickers).

In their collective sensemaking, professional economists, after some initial consternation, decided that the unpredictability of markets is a testament to markets’ ultimate rationality. Individualists who are not economists, however, seem to believe that “The Market” is rational in the sense of being predictable, fair, and efficient—and that they personally (or their proxies) can outsmart it.

CONCLUSION

Paul Rozin (2006, 2007) has wondered what psychology would look like if it focused on the topics people think about every day. As a thought experiment, he asks, what would the chapters of a psychology book look like? Rozin’s own passion (see Rozin, Ruby, & Cohen, [Chapter 17](#), this volume) is food and that would certainly be a chapter, as would time, music, sex, sports, gossip, sleep, and fun. Money and debt would also likely be in there.

Such an introductory psychology book chapter would likely have to take a cross-cultural perspective. Money means something different for the rich and the poor, for people of different ethnic and religious groups, for us versus them, and so on (Cohen, Shin, & Liu, 2019). Undoubtedly,

discussions of money and markets will bring up considerations of “rationality,” but the many meanings of rationality will also have to be untangled: the rationality of cold economic calculation; the rationality of reason overriding emotion and temptation; the rationality of individuals versus that of collectivities and systems; the rationality of rules, efficiency, and calculability; the rationality that overcomes prejudice, superstition, and scapegoating; the rationality of social systems that positively align attitudes and behaviors; the rationality of predictability and comprehensibility; and the rationality of unpredictability. Rationality is not a single, unitary ideal, and conditions enhancing *rationality* in one sense of the word often undermine it in another.

Many other topics concerning how people think about money seem worthy of further exploration: When is money taboo? What can money buy, and what should it not buy (K. Feinberg, 2012; Fiske & Tetlock, 1997; Roth, 2007; Sandel, 2013)? How do we scale, or fail to scale, our qualitative feelings and judgments, our dissonant and ambivalent beliefs, and our trade-offs between incommensurable values onto money’s quantitative metric (e.g., Kahneman, Schkade, & Sunstein, 1998; Shweder, 2001; Viscusi, 2012)? What are the cultural variations in rules of “mental accounting” that turn fungible money into a dedicated, unfungible resource (Thaler, 1985; Zelizer, 2011)? How do different ethnic groups vary in their use of money to gauge social standing and personal success (Cohen, Shin, Liu, Ondish & Kraus, 2017)? And so on.

Along the way, the study can enrich our understandings of how humans behave in circumstances of scarcity (economics’ model) versus those of sufficiency or abundance; how channel factors are crucial for shaping behavior; how people understand what is fair or unfair; and how people set up institutions and intermediaries that bring about desired results—or stand them on their head. In addition to putting us into contact with an important domain of everyday life for many people, the study of how people of different cultures think about money should provide both substantive and more general methodological insights.

NOTES

1. These data generally come from analyses of business bankruptcies rather than consumer bankruptcies, and some measures relate to secured (vs. unsecured) creditors (cf. Martin, 2005). So one should not extrapolate too much from these results. However, on these measures, the ranking of countries is similar to what one might expect given Catholicism's historic animus to interest versus Protestantism's legitimation of it.

2. One of the keys to getting people to extend credit is to give them some assurance that debt collection will be enforced. This was a lesson Paraguay inadvertently learned during the 1990s. Before 1996, it was illegal in Paraguay to write a postdated check. Nevertheless, such checks were commonly written by people and accepted by merchants. The checks were effective collateral, because a creditor knew that he or she could send a defaulting debtor to jail for the illegally postdated (and bounced) check. Postdated checks were such an accepted instrument in Paraguay that there was a secondary market for them (Pagano, 2001).

After a tough recession and a banking crisis, the Paraguayan government tried to relieve the credit crunch, encouraging people to write postdated checks by removing the criminal penalty for doing so. It made the situation worse. What the government didn't seem to realize was that "the criminal sanction was precisely what made postdated checks a viable credit instrument" (Pagano, 2001, p. 6). The limiting factor was not the number of people willing to write postdated checks; it was the number of people willing to *accept* them. The key to jump-starting the credit market was not writing the IOUs; it was reassuring people that the IOUs could be enforced. A similar phenomenon occurred with postdated checks in Brazil. As of 1997, postdated checks have become "the most important source of consumer financing" in Brazil, though enforcement is done through "blacklisting" people who bounce checks rather than throwing them in jail (Castelar Pinheiro & Cabral, 2001, p. 178).

3. Psychologists might have erroneously expected a straightforward attitude– behavior relationship, because they probably mistakenly focus on consumers' demand for credit (e.g., consumers would like to borrow more money, so they act on their desire). This may reflect a disciplinary bias. Interestingly, Frederick (cited in Levitt & Dubner, 2015) proposes that psychologists (and noneconomists) focus on demand-side explanations for phenomena (e.g., more apples are eaten in culture A than in culture B, because people in culture A like apples more); economists, on the other hand, focus on supply-side explanations for phenomena (e.g., more apples are eaten in culture A, because farmers in culture A can grow apples more efficiently). It is likely a useful heuristic to ask how both supply and demand factors may explain a given cultural phenomenon (D. Cohen, [Chapter 6](#), this volume).

4. Unfortunately, this turned into a form of alchemy. Obviously, most mortgages were still okay. However, a fair number of shaky loans were made. There were the famous NINJA loans (No Income, No Jobs or Assets loans). But beyond those known in the industry as "liar loans," lending standards generally were relaxed. According to one estimate from 2006, 46% of mortgages written for first-time homeowners involved *no* downpayment (Calomiris & Haber, 2014). Banks making such loans often had no intention of keeping the loans and would sell them off to, say, an investment bank that bundled loans together into a security for resale. Many of the securities were rated as AAA grade by ratings agencies—who were paid by the organizations that created the securities.

5. It is also consistent with a North American analytic thinking style that predicts continuation of present trends and an Asian dialectical style that predicts cyclicity. In fact, Ji, Zhang, & Guo (2008; Masuda, Russell, Li, & Lee, [Chapter 8](#), this volume) showed price trends to both lay and experienced investors in Canada and China, and found that Canadians predicted continuity, whereas Chinese participants tended to predict reversals. So lay beliefs about change may also partly explain momentum differences in North American and Asian markets.

6. Hindsight bias may lure us into thinking the fall of communism was a foregone conclusion. But from the 1950s on, many best-selling economics textbooks (including Samuelson's 1980 text) predicted that the Soviet Union could surpass the United States within a few decades (Levy & Peart, 2011).

CHAPTER 23

Culture and Work

**Benjamin R. Levine, Jesse R. Harrington, and
Eric Luis Uhlmann***

Our focus in this chapter is on cross-cultural differences in work habits and values, as well as how they are studied. We review national differences in hours worked and work productivity, cross-national surveys on broad dimensions of culture (e.g., power distance, individualism, tightness, survival values), and their relationships to work-related outcomes, as well as social class as a dimension of work culture. Also considered are the unique contributions of experimental approaches to the cultural psychology of work and their utility in probing specific cultural workways, such as *guanxi*, *simpatía*, and Protestant relational ideology. Finally, we discuss future directions for research on culture and work.

With the continued rise of the globalized economy, workplaces are increasingly diverse, multicultural environments (Javidan, Dorfman, De Luque, & House, 2006). Although this presents many new opportunities for businesses and workers, it also presents challenges, most notably, understanding, managing, and leveraging cultural differences. Cultures vary in many aspects, but the focus of this chapter is cultural differences in work habits and values. Bringing together employees from various cultural backgrounds does provide some unique benefits (see Chiu & Hong, [Chapter 26](#), and Leung & Koh, [Chapter 21](#), this volume). However, the complications arising from the multicultural nature of global work often result in team and even organizational conflicts. In addition, these multicultural differences also increasingly lead to the failure of expatriate assignments (Morris,

Fincher, & Savani, [Chapter 18](#), this volume). In this chapter we review empirical studies of some of these key differences and discuss the various ways in which cultural differences in work norms and values are evaluated and studied, as well as future directions for examining those differences through scientific research.

Researchers have employed a multitude of quantitative approaches to study and better understand cultural differences in work-related values and behaviors. These methodologies include cross-national studies of objective indicators (e.g., hours worked per year), cross-national surveys (e.g., self-reported work values), experimental manipulations (e.g., subtly activating a culture's work values using situational cues), and multimethod studies of the workways of specific cultures (e.g., Protestant Relational Ideology in the United States).

WORK HOURS AND PRODUCTIVITY ACROSS NATIONS

Work is an important part of how people spend their lives across the globe. In addition to the fact that work often comprises a significant percentage of an individual's waking hours on a near daily basis, work is often deeply incorporated into people's identities. At the same time, there is a large amount of cross-national variability in the amount of time that people work. According to The Conference Board (2016), a nonprofit business membership and research group organization, Cambodia, Bangladesh, and Vietnam had the highest number of working hours in 2016, with an average of 2,565.01, 2,371.81, and 2,339.95 annual hours per worker, respectively. This translates into approximately 46 hours per week, if divided by 52 weeks. By contrast, the European nations of Norway, Germany, and the Netherlands had the lowest number, with an average of 1,423.93, 1,376.41, and 1,423.02 annual hours per worker, or a weekly approximate average of 27 hours per week.

These national differences in work time are tied closely to productivity. Norway, Germany, and the Netherlands are some of the most productive economies in the world in terms of the adjusted dollar amount produced per work hour, while Cambodia, Bangladesh, and Vietnam are some of the least

productive (The Conference Board, 2016). These examples are demonstrative of a greater general trend. Specifically, there is a substantial negative correlation between hours worked and productivity at the international level, such that lower productivity tends to be related to greater work hours, and vice versa (Our World in Data, 2016). Differences in cross-national productivity, and consequently cross-national work hours, are likely due in part to the broader differences found between the economically developed and developing world. The former often has the latest and most efficient technologies, a highly educated workforce, a strong financial sector to provide capital, and institutions and social infrastructure that encourage productive activities, the accumulation of capital, and a commitment to supporting research and development (Hall & Jones, 1999). Indeed, the low work time and high productivity side of this trend is dominated by the more developed and wealthier Western nations. By contrast, the high work time and lower productivity sector is primarily the domain of many poorer and less economically developed nations from South America, Asia, Africa, the Middle East, and the West Indies. Of course, interpreting the cross-national correlation between work hours and productivity is not entirely straightforward, since different types of work often predominate in these different countries.

Notably, cross-cultural differences in work hours are found not only between modern societies, but also when comparing modern, agrarian-based societies with premodern, hunter-gatherer societies. As demonstrated by anthropologists, labor inputs for the purposes of subsistence in the latter are often fairly small. Indeed, for premodern societies, hours worked per day range from 2.8 hours among the Yanomamo to 7.8 hours among the Tatuyo Amazonian tribes, with an average of about 5.3 hours per day across many premodern groups (Clark, 2008). By contrast, the average working time was approximately 8.8 hours per day in the United Kingdom for the year 2000 (Clark, 2008) and 8.9 in the United States for the year 2014 (Bureau of Labor Statistics, 2015).

The negative relationship between work time and productivity found at the international level also holds at the individual level (Cette, Chang, & Konte, 2011; Pencavel, 2015; Shepard & Clifton, 2000), though for reasons that are based in the limitations of the human animal rather than socioeconomic structures. Indeed, this research indicates that productivity

per work hour has an upper limit, at which point marginal productivity begins to decrease. Using data from British munitions workers during World War I, Pencavel (2015) found this to occur at about 50 hours of work per week. The realities of industrial munitions production, however, are very different than the work in many developed nations today. Indeed, more modern estimations using nations from the Organization for Economic Cooperation and Development (OECD) appear to find this “fatigue effect” in productivity at lower average work times (Cette et al., 2011).

In addition to these findings, research indicates that longer work hours negatively correlate with both physical and mental health, and overall well-being. In particular, longer work hours negatively relate to quantity of sleep (Virtanen et al., 2009a, 2009b) and cognitive function (Virtanen et al., 2009b), correlate with greater incidence of depressive episodes (Virtanen, Stansfeld, Fuhrer, Ferrie, & Kivimäki, 2012b) and increase in coronary heart disease (Virtanen et al., 2010, 2012a), increased risk of diabetes (Kivimäki et al., 2015), and heavier use of alcohol (Virtanen et al., 2015). The correlates of long work hours, as revealed by the variability in work hours across the globe, is suggestive of deleterious effects on human physical and mental health, but whether this relationship is a causal one awaits further research.

Moreover, although the objective measures of work time and productivity are important and informative, there are also significant methodological limitations. In particular, work times in some nations are systematically underreported. In Japan, for example, workers are commonly expected to put in unpaid overtime, which is not accounted for in the two official national assessments of Japanese work hours: the Monthly Labor Survey (MLS) and the Labor Force Survey (LFS) (Mizunoya, 2002). Indeed, some evidence suggests that Japanese workers put in an average of 20 hours of unpaid overtime per month (Mizunoya, 2002). The overburden of work in Japan is enough of a problem that a term exists for people who die or commit suicide from overworking: *karoshi*. Cases of *karoshi* are not uncommon and appear to be on the rise (Reuters, 2016), and there even exists a national hotline for victims of this phenomenon (<http://karoshi.jp/english/activities.html>). Overall, Japan appears to have a work culture that facilitates this expectation of extra hours, which is considerably different from the work cultures of some Western European nations. Contrast norms regarding unpaid and unreported work hours in

Japan with the push in France to limit the expectation for workers to answer e-mails and phone calls outside of work hours (BBC, 2016). This comparison gets to the core point of this chapter, which is that work is dramatically influenced by the norms and values of the cultural contexts that it inhabits. We turn to such cross-national and within-nation differences in values next.

CROSS-CULTURAL DIFFERENCES IN WORK VALUES

Scholars and researchers have increasingly recognized that cultural values influence motivations, behaviors, and perceptions associated with work. In the following, we discuss some well-known studies and frameworks that have identified broad dimensions of cultural values and their relationship with work. At the same time, we emphasize that some differences in cultural values exist above and beyond national boundaries, and are captured by other distinctions, such as social class divisions.

Hofstede's Cultural Value Dimensions

Hofstede (1980a, p. 25) defined culture as “the collective programming of the mind which distinguishes the members of one human group from another.” In the late 1960s and early 1970s, he developed his cultural value framework with data from 116,000 morale surveys completed by 88,000 IBM employees living in 72 countries and regions (reduced to 40 countries that had more than 50 responses each) and speaking 20 languages. Utilizing a country-level factor analysis, Hofstede (1980a) classified the represented countries along four dimensions.

Individualism–Collectivism

The first dimension, “individualism–collectivism,” is defined as the degree to which people in a culture prefer situations in which they identify and act as individuals rather than identify and act as members of a representative

ingroup (Hofstede, 1994). Individualism–collectivism is a cultural value dimension concerning the relation of an individual to the collectives in their society (Hofstede, 1980a). “Collectivism” can be characterized by the subordination of personal goals for collective goals and extended family relationships, and “individualism” refers to the separation from ingroups and independence from others (Triandis, 1995). More simply, individualists tend to operate according to self-interest, whereas collectivists operate according to a group interest. There are many varieties of individualism–collectivism (Triandis, 2001). Horizontal–vertical is one frequently utilized distinguishing aspect of individualism–collectivism, which results in four distinct culture types (Shavitt, Cho, & Barnes, [Chapter 25](#), this volume; Triandis, 2001): (1) horizontal individualism, in which people want to be unique; (2) vertical individualism, in which people want to do their own thing and also to be the best; (3) horizontal collectivism, in which people merge their selves with their ingroups; and (4) vertical collectivism, in which people are willing to sacrifice themselves for their ingroup and submit to the authority of the ingroup. In addition to the vertical–horizontal dimension, many other dimensions define different varieties of individualism and collectivism, and different types of cultures (Triandis, 1995).

Researchers have also spent considerable time determining which regions of the world, and specific groups of individuals, are more individualistic or collectivistic than others (Oyserman, Coon, & Kemmelmeier, 2002). Results from a meta-analysis indicate that, compared to other regions of the world, Europeans and Americans are both more individualistic and less collectivistic than members of other cultures. However, Americans as a whole are indistinguishable on individualism–collectivism from other English-speaking countries.

Individualism–collectivism has become one of the most widely utilized constructs in cross-cultural psychology (Voronov & Singer, 2002), exemplified by diverse and wide-reaching research streams, in which collectivists and individualists have been shown to differ in a variety of aspects (Oyserman et al., 2002; Triandis, 2001). For example, researchers have utilized individualism–collectivism to explain cultural differences in communication styles, such that collectivists are more likely to speak indirectly than individualists (Holtgraves, 1997), and preferred leadership

styles, such that collectivists are more likely to prefer working in teams (House, Hanges, Javidan, Dorfman, & Gupta, 2004; Offerman & Hellman, 1997). Individualists and collectivists also differ in their preferred methods of conflict resolution (Leung, Au, Fernández-Dols, & Iwawaki, 1992; Leung & Fan, 1997). More specifically, in conflict situations, collectivists are primarily concerned with maintaining their relationship with others, whereas individualists are primarily concerned with achieving justice (Ohbuchi, Fukushima, & Tedeschi, 1999). Thus, individualists are willing to forgo or even destroy relationships when settling disputes, whereas collectivists prefer methods of conflict resolution that maintain relationships (Leung & Fan, 1997).

Although initially established and widely examined using self-report surveys across nations, individualism–collectivism has subsequently been investigated by manipulating the microenvironment of the research laboratory. Chatman and Barsade (1995) adapted an organizational simulation to examine interactions between individual and organizational values. Prior to the experiment, participants' collectivistic or individualistic predisposition was assessed based on their responses to a self-report assessment of cooperativeness. As “employees” in the organization, participants were given materials to read, including the company's mission statement and a letter from the company's president. The company description highlighted the organization's reputation as an individualist or team organization, listed valued employee behaviors (cooperation or individual effort), and described how employees would characterize the organization (as team- or individual-oriented). An end-of-year awards celebration was also described that was either for work teams or individuals. During the laboratory simulation, participants performed job tasks in accordance with their roles and worked with other participants. The findings showed that cooperative individuals were more responsive to the individualistic or collectivistic norms of their organization. In the collectivistic condition, the cooperative participants were rated as the most cooperative overall by their coworkers and had the strongest preferences for evaluating their work as a team endeavor rather than as individual achievements. Very interestingly, cooperative individuals were also more responsive to the individualistic norms than were noncooperative individuals. In other words, participants who scored high on trait

cooperativeness behaved more individualistically when organizational values called for individualism.

Other work that selected participants from cultures known to be collectivistic or individualistic in orientation demonstrated that cultural background (e.g., nationality) moderates responses to laboratory situations. For instance, Leung and Bond (1984) conducted a laboratory experiment to determine the influence of cultural collectivism and individualism on reward allocation in public versus private settings. The researchers predicted that in collectivistic cultures, where social norms promote harmony and cohesion, people should be more likely to value equality. In contrast, in individualistic cultures that prioritize individual accomplishments and competition, people will emphasize merit over equality with regard to work compensation. Chinese and American participants were recruited to participate in a work task with a partner. Participants were given a word-copying task and were informed that they would be compensated based on the number of words they and their partner copied by the completion of the allotted time. The participants never met their partners but were told they were working on the same task in the next room. Each participant was asked to divide his or her pay at the end of the work task either equally between him or herself and the partner or based on contribution, in which case he or she would personally receive twice as much money as the partner, since he or she had ostensibly copied more words. Participants made the distribution decision either privately or publicly. In both the public and private condition, U.S. participants, from the more individualistic culture, chose pay based on contribution. The Chinese participants, from the more collectivist culture, chose to divide pay equally, but only in the public condition. In the private condition, Chinese participants chose to allocate pay based on contribution. These findings suggest that a large piece of collectivism rests on reputational concerns.

Experimental studies further demonstrate that individualistic and collectivistic mindsets can be subtly activated and influence judgments and behaviors by affecting the accessibility of an associative network of constructs (Oyserman & Yan, [Chapter 20](#), this volume). Goncalo and Staw (2006) utilized a construct activation procedure to investigate an overlooked benefit of individualistic values and potential downside of a team-based, collectivist organizational culture. As organizations continue to become

more team oriented, they tend to stress collectivist values that reduce social loafing and increase cooperation (Wagner, 1995) and increase identification with work groups (Chatman, Polzer, Barsade, & Neale, 1998). However, Goncalo and Staw (2006) proposed that individualistic values, as opposed to collectivistic values, might better facilitate creativity. To examine the situational effect of individualism–collectivism on creativity, the researchers experimentally manipulated individualistic and collectivist orientations using a survey task, as well as specific instructions to be creative or practical in a subsequent task. For the survey task, participants were randomly assigned to (1) describe why it is beneficial to stand out from others (individualist prime) or (2) describe the groups they belonged to and the similarities between themselves and others (collectivist prime). They were then told to come up with ideas for bringing a new business to a college campus. Half the participants were told that ideas should be practical; the other half were told ideas should be creative. Those told to be creative came up with the most creative ideas—but only when an individualistic mindset was also activated.

A highly effective and ecologically valid means of activating cultural mindsets is with language (Lee, Oyserman, & Bond, 2010). While some researchers believe the tendency to self-enhance is strictly a Western phenomenon (Heine & Hamamura, 2007), others believe it to be universal (Sedikides, Gaertner, & Toguchi, 2003). Lee et al. (2010) contended that self-enhancement is instead related to specific cultural mind-sets. The researchers predicted that participants would be more self-enhancing when an individualistic mindset was made salient by using English than when a collectivistic mindset was made salient by using Chinese. Their participant pool consisted entirely of Chinese students. Across three studies, Chinese students self-enhanced, distanced themselves from outperforming others, and rated themselves better than others, but only when the study materials were presented in English as opposed to Chinese.

Power Distance

The second major cultural dimension identified by Hofstede (1980a), “power distance,” is defined as the extent to which a society accepts

hierarchical relationships, such that power in institutions and organizations is distributed unequally. In a high-power-distance culture, subordinates are not expected to express disagreement with their supervisors, and supervisors are not expected to consult with their subordinates in the decision-making process. Put another way, in low-power-distance cultures, individuals are accustomed to being treated as equals, and those in power are more likely to share their power with those in lower positions. In high-power-distance cultures, power is centralized with fewer individuals who do not share their influence. Cultures or individuals higher on power distance are more likely to value status, influence, and prestige (Schwartz, 1999). Conversely, low-power-distance cultures and individuals value participative decision making and consultative leadership (Hofstede, 1980a).

Brockner and colleagues (2001) investigated the interactive effects of cultural differences in power distance and level of voice in decision-making processes on reactions to work-related outcomes. The procedural justice literature indicates that people often react unfavorably when they have little voice in a decision-making process (Cropanzano & Greenberg, 1997). The researchers conducted four studies investigating whether cultural background moderates this relationship. In Studies 1 and 2, using samples of research participants from the United States, China, and Mexico, participants read a hypothetical vignette informing them that they were members of a company whose department had been rearranged. Participants also read information about their supervisor's decision-making style (the voice manipulation). The researchers manipulated voice by describing the manager's leadership style as being either open to input (high voice) or not open to input (low voice). Participants were asked how much commitment they would feel if they were working at the organization described. Voice was not manipulated in Study 3 or Study 4. In Study 3, participants' from Germany and Hong Kong were asked to describe a recent dispute they were involved in and rate the extent to which they had voice in the dispute. In Study 4, using a sample of Chinese employees, participants were asked to describe their relationship with their direct supervisor at work and rate the extent to which they had voice in the relationship. The findings revealed that participants responded with less organizational commitment to lower levels of voice in relatively low-power-distance cultures (United

States, Germany) but not in relatively high-power-distance cultures (China, Hong Kong, and Mexico).

Cultural differences in power distance are frequently taken into account in research on leadership. Theoretical explanations for the relationship between power distance and leader influence have often diverged (Daniels & Greguras, 2014). Researchers have argued more generally that, as power distance increases, leaders hold more influence over their followers (i.e., Schaubroeck, Lam, & Cha, 2007). However, leaders in high-power-distance cultures who deviate from the inherent distance characterizing typical leader–follower relations are likely to wield diminished influence on employees (House et al., 2004). Transformational leadership (Bass, 1985), leadership characterized by charisma, motivation, and intellectual stimulation (Bass & Avolio, 2004), has received much of the attention in this area, since the prototypical transformational leader theoretically acts antithetically toward the values (i.e., formality and centralized structures) of high-power-distance cultures. Indeed, researchers have found transformational leadership to be less effective in high-power-distance cultures (Kirkman, Chen, Farh, Chen, & Lowe, 2009).

Theoretical work also draws links between the expression of emotions and power distance. For instance, anger may be associated with social status (Tiedens, 2001) and power, but in a manner moderated by target gender (Brescoll & Uhlmann, 2008) and national culture. Park and colleagues (2013) found that higher social status in Japan was positively related to greater expression of anger relative to the United States, where the relationship was negative. Moreover, this relationship in Japan was mediated by decision-making authority. In Japanese culture, then, the use of anger is viewed as a privilege of those higher in social power and as a way of asserting dominance. Notably, in contrast to the United States, anger expression in Japan is related to reduced biological health risks (Kitayama et al., 2015), possibly because it is a marker of social status in Japan rather than a marker of frustration, as in the United States. More generally, subordinates are more likely to suppress their emotions in high-power-distance cultures and organizations (Moran, Diefendorff, & Greguras, 2013).

Uncertainty Avoidance

The third dimension, “uncertainty avoidance,” is the extent to which a society feels threatened by uncertainty and ambiguity, and tries to avoid them by providing greater stability through the establishment of many clear and formal rules (Hofstede, 1980b). It also may be characterized by little tolerance for deviant ideas and behaviors. Uncertainty avoidance is distinct from risk avoidance due to its focus on a society’s tolerance for ambiguity and unstructured situations (Hofstede, 2011). Unstructured situations are novel, unknown, and different from the usual. Uncertainty-avoiding cultures utilize strict behavioral codes, laws, and rules in an attempt to minimize the possibility of such situations. People in uncertainty-avoiding countries tend to be more emotional and motivated by inner nervous energy (Hofstede, 2011). Uncertainty-accepting cultures have fewer rules and are more tolerant of different opinions. East and Central European countries, Latin countries, German-speaking countries, and Japan tend to be more uncertainty-avoidant cultures (Hofstede, 1980a, 2001). English-speaking, Chinese, and Nordic cultures tend to be higher in uncertainty acceptance.

Masculinity–Femininity

The final of the original Hofstede dimensions is masculinity–femininity. “Masculinity” can be defined as the extent to which the dominant values in a society are stereotypically masculine, such as assertiveness and competitiveness, while “femininity” is the dominance of stereotypically feminine values, such as security and cooperation (Hofstede, 1980b). It also refers to the distribution of values between genders in a society (Hofstede, 2011). Research in this area has illustrated that men’s values can vary greatly between cultures, from assertive to modest and caring, and women’s values tend to be markedly more similar across cultures (Hofstede, 1980a, 2001). In more feminine cultures, men and women share the more “feminine” modest and caring traits. In contrast, in more masculine countries, there is a larger gap between the values of men and women. Additionally, in masculine cultures, there is often a taboo around this dimension (Hofstede, 1998). Masculinity tends to be higher in Japan, German-speaking countries, and some Latin countries, and is moderately high in English-speaking and

Western countries. It is low in Nordic, Asian, and some Latin countries (Hofstede et al., 2010).

State of Research

Research on cultural values, especially work by Hofstede (1980a, 1994), pushed forward previous cross-cultural research in which geography was used as a proxy for culture (Gelfand, Nishii, & Raver, 2006). However, researchers have also concluded that there has been an overreliance on individualism–collectivism compared to Hofstede’s other value dimensions (Gelfand et al., 2006; Tsui, Nifadkar, & Ou, 2007). Taras, Kirkman, and Steel (2010) also reviewed the state of work conducted on Hofstede’s four cultural dimensions. They found, at the individual level of analysis, that the four value dimensions predict outcomes with similar strength. They also found that cultural values were most strongly related to emotions, followed by attitudes, behaviors, and finally job performance. Additionally, the predictive power of the cultural values was significantly lower than that of personality traits and demographics for some outcomes (e.g., job performance, turnover), but significantly higher for others (e.g., organizational commitment, team-related attitudes).

Just as importantly, Hofstede’s cultural dimensions are related to work outcomes in theoretically meaningful ways (Kirkman, Lowe, & Gibson, 2006; Taras et al., 2010). Individualism, relative to collectivism, is negatively related to group cohesiveness and preference for teamwork, lower cooperation and compromising, less organizational citizenship behaviors, lower organizational commitment, poorer joint gains in negotiation, and poorer group performance (Arunachalam, Wall, & Chan, 1998; Moorman & Blakely, 1995; Van Dyne, Vandewalle, Kostova, Latham, & Cummings, 2000). However, individualism is also related to stronger avoidance of unethical behavior and greater directness of communication. Power distance is related to greater cooperation, more organizational commitment, lower feedback seeking, and less avoidance of unethical behavior. Uncertainty avoidance is related to greater cooperation, greater reliance on established norms and protocols, lower innovation, and greater organizational commitment and team commitment (Shane, Venkataraman, & MacMillan,

1995). Finally, masculinity (relative to femininity) is associated with poorer team cooperation, less cooperative negotiation behaviors, greater directness, less conflict avoidance, less avoidance of unethical behavior, and greater preference for inspirational leadership behavior (Steensma, Marino, & Weaver, 2000; Taras et al., 2010).

Taras and colleagues' (2010) review also indicated that cultural values are more strongly related to work outcomes for older, male, managerial, and more educated respondents. They hypothesized that this amplification of cultural values is due to the greater crystallization of individual cultural values. In other words, people develop and learn particular behavioral and cognitive patterns stemming from these values through consistent use. Over time, these patterns become more and more "crystallized" or automatic in nature—they come to dominate the way that individuals approach, think about, and perceive the world, and amplify the effect that these cultural values have on their behavior. This is particularly likely to happen as one grows older, if one has a more agentic self-construal (which is more common in men than in women), and through participation in institutions in which one acquires more leeway in letting one's values determine behavior (i.e., when one is more highly educated or in a managerial position within an organization).

Hofstede subsequently added two more cultural dimensions to his framework: long-term versus short-term normative orientation and indulgence versus restraint. The first describes cultures that are oriented toward future rewards versus those that maintain traditional norms and are more oriented toward present gratification (Hofstede, 2001). This dimension was first identified by Bond and colleagues (Hofstede & Bond, 1984; Hofstede & Bond, 1988) in Taiwan and Hong Kong and has been linked to the fast pace of economic growth in those places (Hofstede, 2001). The second describes cultures with an orientation toward unimpeded enjoyment and fun versus those that suppress and regulate these behaviors through strict social norms. While these two dimensions may seem conceptually similar, indulgence versus restraint is more about the feeling of control people have over their lives. Consequently, it is entirely possible for cultures to grant people a great deal of personal control over their lives (indulgence), while still motivating them to think about their behavior in a long-term

fashion. For example, Luxembourg and Germany are nations that are relatively high on both dimensions.

The GLOBE Research Project

The Global Leadership and Organizational Behavior Effectiveness (GLOBE) project began in the 1990s and has progressed into an enormous research effort, utilizing over 200 researchers from a variety of disciplines all over the globe (Dorfman, Javidan, Hanges, Dastmalchian, & House, 2012). The team has collected data from over 15,000 participants in nearly 100 countries. GLOBE's purpose was and continues to be exploration of the complex effects of culture on leadership and organizational effectiveness. The research built on lay theories of leadership—otherwise known as “implicit leadership theory” (Lord & Maher, 1991)—to develop a culturally sensitive theory of leadership (House et al., 2004). The GLOBE project has three phases (Dorfman et al., 2012). Phases 1 and 2 implemented a multimethod program to examine the relationship among national culture, leadership effectiveness, and societal phenomena. The purpose of Phase 3 is to determine the manner in which national culture influences executive leadership processes.

The GLOBE Leader Attributes and Behavior Questionnaire was the primary leadership survey instrument utilized in Phases 1 and 2 (Dorfman et al., 2012). The final version included 112 leader attribute and behavior items, which included a wide variety of traits, skills, behaviors, and abilities potentially relevant to leadership emergence and effectiveness. Participants rated all 112 attributes on a 1- to 7-point scale, with 1 indicating “this behavior or characteristic greatly inhibits a person from being an outstanding leader” and 7 indicating “this behavior or characteristic contributes greatly to a person being an outstanding leader” (House et al., 2004). The ratings were then utilized to inform statistical grouping procedures that resulted in the formation of 21 primary dimensions of leadership (House et al., 2004). A second-order factor analysis of the 21 dimensions produced what the GLOBE research team refers to as the six culturally endorsed leadership theories (CLTs) or global leadership dimensions (House et al., 2004).

These six global dimensions are charismatic/value-based leadership, team-oriented leadership, participative leadership, humane-oriented leadership, autonomous leadership, and self-protective leadership (House et al., 2004). Charismatic leadership reflects the ability to inspire, to motivate, and to expect high performance outcomes from others based on firmly held core values. Team-oriented leadership emphasizes effective team building and implementation of a common purpose or goal among team members. Participative leadership reflects the degree to which managers involve others in making and implementing decisions (House et al., 2004). Humane-oriented leadership reflects supportive and considerate leadership and also includes compassion and generosity. Autonomous leadership refers to independent and individualistic leadership attributes. Finally, self-protective leadership focuses on ensuring the safety and security of the overall group and its individual members through status enhancement and face saving.

The findings of the GLOBE research project provided support for the relationship between culture and leadership prototype content (Dorfman et al., 2012). For example, researchers have found that leadership prototypes vary by the respondent's home country (Gerstner & Day, 1994; Hanges & Dickson, 2004; House et al., 2004), and national culture influences leadership behaviors through a society's expectations of a leader's behavior (Dorfman et al., 2012). House et al. (1999) argue that culture is a major determinant of the commonality found in leadership prototypes for individuals within the same cultural group. GLOBE researchers were able to demonstrate that culturally similar societies can be clustered together (Gupta & Hanges, 2004) with meaningful differences in the content of the CLT profiles (Dorfman, Hanges, & Brodbeck, 2004). These CLT dimensions represent societal-level leadership characteristics. For example, the United States and England are both in the Anglo cluster of countries. These countries scored higher on the CLT dimensions of Charismatic, Participative, Team, and Humane-Oriented Leadership and lower on the CLT dimensions of Autonomous and Self-Protective leadership. In contrast, China, a country in the Confucian Asia cluster, scored higher on the CLT dimensions of Self-Protective, Autonomous, and Humane Leadership, and lower on the CLT dimensions of Charismatic, Team, and Participative Leadership. The researchers also identified a number of universally endorsed leader characteristics that were rated by 95% of the countries in their dataset

as contributing to outstanding leadership (House et al., 2004). Overall, the GLOBE research project has contributed to our understanding of the relationship between national cultural values and leadership expectations in the workplace (Dorfman et al., 2012).

The World Values Survey and the Inglehart–Welzel Cultural Map

The political scientists Ronald Inglehart and Christian Welzel have devised another framework for understanding national differences in culture through their analysis of data collected by the World Values Survey (WVS). This survey uses a common questionnaire to collect nationally representative samples across approximately 100 nations and has been in use since 1981. It is currently on its seventh wave of data collection. Each wave takes approximately 4 years to complete. Based on their analysis, Inglehart and Welzel (2005; World Values Survey, 2016) suggest that there are two major axes of cultural variation: traditional versus secular–rational values and survival versus self-expression values. “Traditional values” are characterized by a high emphasis on religion, traditional family values, deference to authority, and national pride, and rejection of divorce, abortion, euthanasia, and suicide. By contrast, “secular-rational values” place less emphasis on religion, traditional family values, and authority, and are more accepting of divorce, abortion, euthanasia, and suicide. On the other axis, “survival values” are characterized by an emphasis on economic and physical security and low levels of trust and tolerance. “Self-expression values” are characterized by greater tolerance of others, gender equality, environmental protection, and more equitable participation in economic and political decision making. Wealthier nations tend to have higher secular–rational and self-expression values, while economically poorer nations tend to have higher traditional and survival values. As nations become wealthier and standards of living improve, an individual’s existential security and sense of individual agency both increase, causing general cultural shifts from traditional and survival values to secular–rational and self-expression values (Inglehart & Welzel, 2005; World Values Survey, 2016). However, all combinations between the two axes are possible. For example, the United

States and Latin America are high in traditionalism and self-expression, while much of Eastern Europe is high in secular-rational and survival values, likely due in part to the influence of communism.

Differences on these values have been found to impact perceptions of work. Snir and Harpaz (2009) found that individual “work investment”—perceiving work to merely be a way of earning money—is greater in countries where survival values are high relative to countries with greater self-expression values. By contrast, “work devotion”—perceiving work to be an enjoyable pursuit above and beyond money—is greater in countries where self-expression values are high relative to countries with greater survival values. Job security is also more highly prized in countries with survival values (Inglehart & Oyserman, 2004). Finally, the findings concerning the relationship of Hofstede’s individualism–collectivism to work may also apply to the axis of survival versus self-expression; research suggests that they tap a similar underlying construct (Inglehart & Oyserman, 2004; Hofstede, 2001). Indeed, national mean scores on measures of both constructs are found to factor together and are correlated at approximately .66.

Tightness–Looseness

Tightness–looseness denotes the *strength of norms* and *tolerance for norm deviance* in a given cultural collective; *norm strength* denotes the breadth of unwritten and institutionalized rules that exist, as well as the degree of social and institutional pressure that individuals feel to follow them, and *tolerance for norm deviance* denotes the amount of punishment that results when norms are violated (Gelfand et al., 2011). By definition, tight cultural collectives have high norm strength and low tolerance for deviance, while loose cultural collectives have low norm strength and high tolerance for deviance. As a construct, tightness–looseness was first devised in the field of anthropology (Pelto, 1968) and has since been extensively researched and developed into a theory of culture by Gelfand and colleagues (2006, 2011). This includes (1) extensive theoretical discussion about tightness–looseness and its relationship with societies and organizations (Gelfand et al., 2006), and (2) work demonstrating significant cultural variability on tightness–

looseness between nations and its relationship with ecological threat and a variety of interrelated psychological variables (Gelfand et al., 2011; Gelfand, Harrington, & Fernandez, in press). Prototypically tighter nations include Pakistan, Singapore, and Turkey, and prototypically looser nations include Ukraine, the Netherlands, and Brazil. Tightness–looseness is related to but distinct from other cultural dimensions—for example, tightness is correlated with Hofstede’s individualism at $-.47$.

Tightness–looseness relates to work in a variety of ways. Using meta-analysis, Taras et al. (2010) found that societal tightness–looseness moderates the effect that other cultural dimensions have on organizational outcomes. More specifically, the relationship between cultural dimensions and various organizational outcomes was stronger in tighter versus looser nations. Crossland and Hambrick (2011) found that national tightness–looseness influences chief executive officer (CEO) discretion. As predicted, given the higher constraint in tighter societies, CEOs have comparatively less discretion in tighter nations. Lower discretion, in turn, was associated with a weaker influence of CEO actions on organizational performance. Other researchers have found evidence that tightness increases behavioral synchronicity. In particular, Eun, Wang, and Xiao (2015) found that tighter countries exhibit more stock price co-movement or “herding,” which is linked to lower marketwide and firm-specific variation in these societies. In other words, the stronger normative values and conformity that exist in tighter societies lead individuals to follow the pack when deciding how to invest their money.

Industrial–organizational psychologists have also investigated the relationship between tightness–looseness and creativity, an issue that impacts innovation (Chiu & Hong, [Chapter 26](#), this volume). Chua, Roth, and Lemoine (2015) found that individuals from looser cultures are better at engaging and succeeding on creative tasks from foreign cultures, while individuals from tighter cultures do poorer on foreign creative tasks and are less receptive to creative ideas from foreign cultures. This is consistent with evidence from Harrington and Gelfand (2014), who found poorer creativity outcomes for tighter states in the United States. However, when working on local creative tasks from their own country or from other culturally tight nations, individuals from tighter nations performed well (Chua et al., 2015).

Finally, researchers have also examined the relationship between tightness–looseness and leadership. Toh and Leonardelli (2012) found that tighter nations generally had fewer women emerge into top leadership positions relative to looser nations, primarily because increased tightness engenders greater resistance to changing the traditional notion that leaders are men in many cultures. However, they also found that when egalitarian norms are culturally predominant, tighter nations exhibit greater leadership emergence for women relative to looser nations. Tight and egalitarian nations in this data include Norway, Singapore, and Portugal. In summary, tightness appears to sustain existing practices due to strict implementation and enforcement, egalitarian or not. Aktas, Gelfand, and Hanges (2015) found that tightness–looseness influences perceptions of effective leadership. Using national tightness–looseness data from Gelfand and colleagues (2011) and leadership preferences from the GLOBE Study (House et al., 2004), they predicted and found that tightness is positively related to the endorsement of autonomous leadership (i.e., leaders who make independent decisions without relying on others) and negatively related to the endorsement of charismatic and team-oriented leadership, even after controlling for other dimensions of culture such as power distance and individualism–collectivism. The researchers surmise that autonomous leadership (vs. team-oriented leadership) is valued in tighter societies because it produces quick decision making and generally reinforces the status quo, which is a boon for those with a greater psychological need for closure. The researchers also suspect that the visionary and inspirational tactics associated with charismatic leadership, which often upset the status quo, are viewed negatively in tighter cultures, because they tend to be counter to the dominant prevention orientation of those societies. However, this is also the reason that individuals in looser cultures, which are often more open and innovative, view charismatic leadership styles as more effective.

Social Class and Work

While much of the research and theorizing about the interface of culture and work have understandably focused on nationality, it is also important to recognize that culture is not the exclusive purview of national differences.

Indeed, regional differences are incredibly common within nations (see, e.g., Rentfrow & Jokela, [Chapter 29](#), this volume). Indeed, cultural differences in collectivism–individualism have been found in the United States (Vandello & Cohen, 1999) and Japan (Kitayama, Ishii, Imada, Takemura, & Ramaswamy, 2006), the U.S. South has been identified as an honor culture relative to other areas of the country (Nisbett & Cohen, 1996), and U.S. states and regions have been found to differ substantially in tightness–looseness (Harrington & Gelfand, 2014), to mention but a few examples. Anecdotes abound outside of the research literature as well. Within Spain, Catalonia is very different culturally compared to Galicia, and the local culture experienced by an individual from Xinjiang in Western China is very different than that experienced by someone in Shanghai.

Another important cultural distinction that goes beyond the focus on national differences is social class. Extensive research has identified wide-ranging cultural differences between the middle class and the working class, particularly within the United States. Relative to the middle class, the working class tends to have a greater preference for interdependence and relational orientation (Markus & Hamedani, [Chapter 1](#), this volume; Stephens, Fryberg, Markus, Johnson, & Covarrubias, 2012; Stephens, Fryberg, & Markus, 2011; Snibbe & Markus, 2005) and a prioritization of behavioral conformity to externally defined standards (e.g., obedience to parents, neatness/cleanliness) rather than a concern for the internal processes of both the self and others (Kohn, 1969). This is likely due to the day-to-day economic situation of working-class life. Indeed, the realities of low income and low social mobility often necessitate and produce increased closeness to family, friends, and community in working-class communities. Relying on others to survive, for material and social support, and to get by when times are tough is a common occurrence. It is also adaptive for people low in social status and power to conform to the demands of authorities who can punish or withhold resources. Furthermore, it has been found that working-class individuals tend to rely on greater contextual and fewer dispositional explanations for a variety of phenomena (Grossmann & Varnum, 2011; Varnum, Na, Murata, & Kitayama, 2012). This makes logical sense given how influential context may be in working-class communities, where the external limits of one's employment status, income, and

educational opportunities impact outcomes to a greater degree than in middle-class communities.

Notably, it has been found that many of the cultural differences between the American middle and working classes also appear to map well to social class differences outside the United States. The working-class value of conformity has been found in cultures as different as Italy (Kohn, 1969), Poland and Ukraine (Kohn et al., 2002), and Japan (Kohn, Naoi, Schoenbach, Schooler, & Slomczynski, 1990), even after researchers controlled for religious background, religiosity (i.e., church attendance), nationality, race, region, urban versus rural location, and the age of the person in question (Kohn, 1969). Likewise, Grossmann and Varnum (2011) found that the decrease in dispositional bias among the working class also occurred in Russia, a country with very different national value orientations relative to the United States (Hofstede, 1980b; Grossmann & Kross, 2010; Kühnen et al., 2001; Nisbett, Peng, Choi, & Norenzayan, 2001). All of this indicates that social class is a very important cultural distinction in general, and its implications for understanding the interface of culture and work may be just as important as for understanding national differences.

Most importantly, the type of work that the working class and the middle classes do is very different, so much so that it often comprises an important part of their identities. Indeed, members of the working class tend to have low status, physically oriented “blue-collar” occupations that offer a significant possibility of injury, dismemberment, or death on a daily basis (DiMaggio, 2012; Levison, 1974). Given how difficult this work can be, the working classes often laud the values of self-discipline and perseverance, and many take pride in doing “real work,” something that they feel most people, particularly those from white-collar backgrounds, cannot or will not do (Lamont, 2000). They also face a higher degree of supervision and structure in their workplaces (Kohn, 1969; Schooler, 2007) relative to the middle class. By contrast, the “white collar” middle class tends to have occupations that are higher status, more unstructured, less physically intensive, and less physically dangerous (DiMaggio, 2012).

The type of work that each class group does may be the linchpin that causes social class cultural differences. As demonstrated by Kohn (1969) in his seminal study of class differences, the differences in supervision, structure, and type of work between the working class and the middle class

lend themselves to very different sets of values and perceptions of one's place in society. The high supervision, structure, and routinization of working-class occupations, for instance, often necessitate conformity to authority and rule abidance. These occupational factors predict greater authoritarian conservatism, greater endorsement of traditionalism and resistance to change, and greater belief in the influence of external forces on one's life. By contrast, the low supervision, structure, and routinization of middle-class occupations foster a greater emphasis on self-direction and cultivate a greater belief in innovation and change, and a stronger internal locus of control. Ultimately, both groups teach their children these particular sets of values, which prepare them for their future life as a member of a similar occupational environment (see Nisbett, [Chapter 7](#), this volume).

Each class also has very different approaches and motivations toward work. The lower income and lower status of working-class occupations in a society that more often lauds the contributions and importance of middle-class occupations means that working-class people tend to conceive of an occupation as “job” rather than a “career” (Argyle, 1994). Combined with the specter of sliding into poverty or “hard living” (Howell, 1972; Williams, 2012), this lends itself to viewing an occupation as a means to an end rather than an end itself. Indeed, this typically results in working-class people placing a higher value on family before work (Williams, 2012), compared to people in the middle class.

Other predictions about the interface of social class cultural differences and work can be derived from this prior theoretical and empirical research. For example, cultural values may impact attraction and retention of individuals from different class backgrounds. As demonstrated by Stephens et al. (2012), working-class individuals are primarily motivated to acquire a university education for more interdependent reasons (e.g., helping their family and community). However, given that universities and colleges are primarily middle-class institutions, they often promote individualistic values (e.g., personal achievement) in their messaging and mission statements. The cultural mismatch that results has been shown to negatively impact the outcomes and success of working-class university students in longitudinal research (Markus & Hamedani, [Chapter 1](#), this volume). Similar value mismatch within work environments or organizations may likewise impact members from incongruent class groups. This is in line with much

theorizing and research on the attraction–selection–attrition model (i.e., employees are attracted to, selected for, and more likely to stay in organizations that fit their values and attributes; Schneider, 1987). Overall, how social class culture impacts work across the world remains an important area for future research.

SPECIFIC CULTURAL WORKWAYS

“Workways” describe the unique and signature pattern of workplace beliefs, mental models, and practices that embody a specific society’s ideas about what is true, good, and efficient within the domain of work (Sanchez-Burks & Lee, 2007). One major focus of research on cultural workways is “workplace relational styles” (Sanchez-Burks & Lee, 2007), which refer to people’s beliefs about the function of relationships in the workplace, as well as relational behaviors at work that reflect deep-seated ideologies about the nature of socioemotional ties within and across work domains. The following section highlights some key cultural workways and presents empirical research related to relational styles in each case.

Guanxi

Guanxi is the dominant relational norm of Chinese organizations, in which business relations are characterized by a distinct emphasis on building dense networks of personal relationships (Sanchez-Burks & Lee, 2007). Workers often conduct their business by making their social connections available to one another. This dense system of networks that characterizes the Chinese workplace differs from networking in Western businesses because of its transitive nature (Cai, 2001; Li, Tsui, & Weldon, 2000). Whereas a Western businessperson may ask a colleague to facilitate a new connection, a Chinese businessperson operating under *guanxi* would assume that he or she has direct access to any person in a colleague’s network. Due to the importance of social networks, it is also common for a Chinese businessperson to work with another person simply because they have a mutual acquaintance, because this is seen as a reassurance that the partner will be reliable

(Sanchez-Burks & Lee, 2007). For many Chinese professionals, establishing *guanxi* is an essential condition to an effective working relationship (Sanchez-Burks & Lee, 2007).

Farh, Tsui, Xin, and Cheng (1998) investigated the importance of *guanxi* and relational demography on trust in Chinese workplace relationships. “Relational demography” refers to similarities or differences between an individual and others on a variety of factors, including age, gender, race, religion, education, and occupation. In Study 1, 560 supervisor–subordinate dyads completed surveys containing measures of trust in the supervisor, commitment to the organization, subordinate performance, relational demography factors, and *guanxi*. *Guanxi* was measured in a checklist-style format in which both the supervisor and subordinate were asked if their specific dyad represented *guanxi*. If both partners in the dyad responded “yes,” the dyad was marked as having *guanxi*. Study 1 results indicated that *guanxi* was related to trust in a supervisor, a result replicated in Study 2 with a sample of executives. Overall, their findings across both studies illustrated that *guanxi* is a key factor in developing trust in Chinese business relationships, over and above demographic similarities.

Simpatía

In Latin cultures, the relational script of *simpatía* is thought to guide workplace relationships (Diaz-Guerrero, 1967; Sanchez-Burks, Nisbett, & Ybarra, 2000; Triandis, Marín, Lisansky, & Betancourt, 1984). *Simpatía* emphasizes social harmony, to the extent that understanding and respecting others’ feelings is valued above other concerns (Markus & Lin, 1999). Although this is similar to many East Asian cultures, *simpatía* also emphasizes expressive displays of personal charm and hospitality in work contexts (Sanchez-Burks & Lee, 2007).

Ramírez-Esparza, Gosling, and Pennebaker (2008) conducted an experimental study examining the effects of language on warm and agreeable interpersonal behavior. Bilingual Mexican Americans engaged in mock interviews in Spanish or English with a videotaped actor. Independent judges, unaware of the language in which the interview took place, rated the number of *simpatía*-related behaviors participants engaged in during their

interactions. Overall, bilinguals performed more *simpatía*-related behaviors when the task was performed in Spanish as opposed to English.

Protestant Relational Ideology

Workways in the United States differ from the culture-specific relationship styles outlined earlier, in that they do not share the same emphasis on relationships at work (Sanchez-Burks & Lee, 2007). The Protestant relational ideology (PRI), an ideology that combines teachings about the importance of work with Calvinist imperatives for restricting relational concerns while working, guides American relational styles (Sanchez-Burks, 2002). The PRI is characterized by a divide in relational attunement, or attention to affective issues and relational concerns, between work and nonwork contexts (Bendix, 1978). Specifically, relational attunement among Americans is reduced in work settings compared to social, nonwork settings (Sanchez-Burks, 2004).

One of the main contributions of PRI was to provide a theoretical framework that explains why and when Americans' interpersonal style differs from other cultural groups not rooted in Calvinist Protestantism (Sanchez-Burks, 2004). Over two experimental studies, Sanchez-Burks (2002) investigated the influence of PRI on emotional expression and relational focus inside and outside of work settings. In the first study, individuals participated in groups of four. All participants were either Protestant or Catholic. The groups were randomly assigned to work or nonwork contexts by dressing the participants formally, in business shirts, or informally, in Hawaiian shirts. In the formal condition, participants discussed a business case. Participants in the informal condition played a game. After discussing the case or playing the game, participants were directed to individual cubicles. Once separated, participants responded individually to a vocal Stroop task (Kitayama & Ishii, 2002) in which they judged the pleasant or unpleasant valence of spoken words, some of which were positive and others that were negative in meaning. Critical trials were those in which the literal meaning of a word was contradicted by the affective tone of voice in which it was spoken (e.g., the word *joyful* spoken in a sad voice). Attunement to emotion would be reflected in delays on critical

trials, as participants would have difficulty separating out the meaning of the word from the way it was said. Results indicated that individuals raised in the Protestant tradition were less automatically attentive to affective tone of voice when a work context had recently been activated.

In the second study, participants took part individually. In the formal condition, the experimenter asked participants to dress for their session as they would for an important business interview. Participants in the informal condition dressed for a regular class. During the session, all participants worked with a research confederate on a shared task. The confederate was instructed to continuously shake his or her leg throughout the entire task. A measure of the participant's physical mimicry of the confederate, specifically, leg shaking, was the dependent variable. The findings suggested that within a work setting, Protestant males exhibited less relational focus than did males from non-Protestant groups and women in general, in that they engaged in less nonverbal mimicry. However, in social, nonwork contexts, Calvinist Protestants were just as likely to create a nonverbal rapport through mimicry as were non-Protestant Americans (Sanchez-Burks, 2002).

Summary

Research on cultural workways goes into great depth to identify the specific mental models individuals from a given culture utilize to manage relationships in the workplace. Certain workplace relational styles, such as *guanxi* and *simpatía*, rely on a heightened sensitivity to interpersonal relationships and emotional stimuli in the workplace, consistent with collectivistic values. But at the same time, they do so in distinct ways, with *simpatía* emphasizing interpersonal agreeableness and humor, and *guanxi* more focused on long-term network ties. Other cultural workways, such as PRI, are steeped not only in individualism but also in cultural history and religious traditions that place much less importance on relational concerns in work contexts. Although some scholars have argued that the globalization of the workplace may have reduced cross-cultural differences, and that the world of work has begun to resemble a culture-free zone (Birnbaum-More & Wong, 1995), experimental research on workways suggests that cultural

differences may actually be amplified in work contexts (Sanchez-Burks & Lee, 2007; Sanchez-Burks, 2002).

CONCLUSION

Work is an important component of people's lives across cultures. Hence, it is important to understand the cross-cultural differences and similarities in how work is approached, conducted, and perceived the world over. In this chapter, we have attempted to distill our current understanding of the relationship between work and culture, and to review the many complementary approaches used to investigate it, including studies of objective indicators such as work hours and productivity, cross-national surveys of self-reported work values, and experimental approaches. These studies have identified important differences across and within nations in work behaviors and values, as well as their interactions with individual dispositions and situational factors. Multidisciplinary studies of specific cultural workways have further examined how the unique histories of certain countries have shaped the work values of those societies, as in the case of PRI in the United States.

Research in this area identifies unique ideologies that shape cultural understandings of how people should think, feel, and act with regard to their work. These are critical for understanding how and why cross-cultural differences emerge and when they may be problematic for intercultural relations. Given work's dominant place in the center of everyday life, understanding the cultural psychology of work is a critical component in managing the intercultural contact that forms the backbone of the modern workplace, where individuals must coordinate and cooperate despite deep-seated cultural differences. All in all, research on culture and work will continue to be an impactful and fascinating area of inquiry for many years to come.

CHAPTER 24

Cultural Psychology of Negotiation

Michele J. Gelfand and Joshua Conrad Jackson

Cultural influences on negotiation are responsible for some of the most important and tragic moments in human history. However, the field of negotiation has only recently begun to study how negotiation processes vary across cultures, and why intercultural negotiations can be so difficult. This chapter provides a comprehensive synthesis of research on culture and negotiation. After outlining important terms and key findings in the negotiation literature, we review (1) how culture influences negotiators' emotions, motivations, and cognitive biases; (2) how culture influences negotiators' strategies; (3) how cultural differences in negotiation are moderated by contextual factors; (4) new insights into intercultural negotiations and multicultural teams; and (5) cultural differences in mediation. We close the chapter by highlighting future directions in research in negotiation and culture, involving both new theory and new methods. We hope that this chapter serves as not only a review of existing research in culture and negotiation but also as a catalyst for the field's future.

On July 11, 2000, Bill Clinton, Ehud Barak, and Yasser Arafat gathered at Camp David in the wooded hills of Maryland. Their meeting had a solemn goal: to bring an end to the devastating struggle between Israelis and Palestinians for land and sovereignty. It also had an air of desperation. Arab and Israeli leaders had been meeting for over 30 years, but each peace deal had been followed by new hostilities. The 1993 Oslo Agreement—in which Israel and the Palestinian Liberation Organization formally recognized the

other's statehood and agreed to put an end to conflict—had been rejected by the Palestinian Hamas group and many Israeli settlers. With the left-wing Barak's term ending and Clinton's presidency nearing its completion, the 2000 Camp David Summit took on a sense of finality. "There is no guarantee of success," Clinton said at the meeting's opening press conference, "but not to try is to guarantee failure." He concluded the conference by expressing hope for the "gift of peace," but 2 weeks later, the Camp David negotiations deadlocked and dissolved. Within a year, the hard-line Ariel Sharon had replaced Barak as prime minister, and suicide bombings by Palestinian military groups and counterattacks from Israel had intensified.

There is no single reason why the talks at Camp David failed. The history of Arab–Israeli negotiation is one of the most complex topics in international affairs. Yet many of the reasons why this particular negotiation stalled were tied to cultural differences. For example, Clinton's desire for quick and intense negotiations was characteristic of Western negotiation styles, in which time means money (Salmon et al., 2016). However, it also forced Barak and Arafat into repeated close encounters over sensitive issues, and didn't allow the kind of rapport building that is fundamental to building trust in the Arab region (Gelfand et al., 2015). Additionally, Arafat's refusal to make a counteroffer to Barak's initial proposal frustrated and perplexed many Israeli and American analysts, but it was characteristic of a Middle Eastern culture of honor, where symbolic concessions are viewed as signs of weakness and entail dire reputational costs. Arafat could not afford to show any such weakness, particularly in public, with many Arab leaders scorning his decision to negotiate in the first place and Arabs around the world protesting the possibility of concessions.

These same miscommunications have characterized countless previous negotiations. For example, peace in Vietnam was nearly compromised when American and Vietnamese negotiators calculated vastly different timetables for agreement—American representatives booked their hotel for a week, while the Hanoi team rented a chateau for a year (Adler & Gundersen, 2008). More recently, analysts noted that Iran may have taken advantage of Americans' impatience and purposefully stalled negotiations over the 2015 nuclear deal in order to win better economic and military terms (Logiurato & Kelley, 2014). By stalling talks, Iranians could take advantage of increased domestic pressure for Barack Obama to reach a swift nuclear compromise,

while also leveraging a gradually recovering economy after gaining relief from some sanctions during an earlier 2013 deal. Cultural differences consistently lead to these sorts of negotiation breakdowns, yet their role is often ignored.

Our goal in this chapter is to underscore culture's critical role in negotiation by summarizing research on the topic from the past five decades. Before reviewing cultural influences on negotiation, we begin by defining key terms that we use throughout the chapter. Next, we provide a brief history of the different traditions of negotiation research and findings therein. We then explore numerous ways in which culture shapes psychological and social processes in deal-making negotiation and disputes, both in intercultural and intracultural negotiations. Finally, we identify unexplored areas of research for culture and negotiation, and highlight limitations and future directions for the field.

FUNDAMENTAL DISTINCTIONS

Defining Negotiation

While negotiations are diverse in their content and context, they also share certain elements (Gelfand, Fulmer, & Severance, 2010). Negotiators usually perceive a conflict of interest and are engaged in communication to divide and exchange resources. These resources may be tangible (e.g., money) or intangible (e.g., respect). In negotiation, compromises are usually possible, and the nature of these compromises is determined through offers and counteroffers. Perhaps most importantly, individuals in a negotiation are interdependent, and their negotiation outcomes are determined jointly (Chertkoff & Esser, 1976; J. Cross, 1965; Rubin & Brown, 1975).

Similarities notwithstanding, negotiations vary widely in their nature. Negotiators' personal interests may either be diametrically opposed (distributive), or reconcilable through trade-offs (integrative). This distinction has critical implications for people's available and preferable negotiation strategies. In "distributive negotiations," opponent's gains come at one's own expense, a structure that is termed "fixed sum" (Pruitt, 1981). Consequently, distributive negotiations do not feature a search for trade-offs

and are generally associated with competition and only a concern with one's own outcomes (Carnevale, Pruitt, & Seilheimer, 1981). In contrast, "integrative negotiations" feature opportunities for trade-offs when parties do have different interests but very different priorities on the issues. Imagine a husband and wife trying to choose where to go on vacation (Pruitt, 1986). The husband wants to go to a cabin in the mountains, and his wife wants to go to a beachfront resort. At first, their preferences do not seem reconcilable, but a closer look reveals two issues at stake: the location and the accommodation. The wife might be searching for a great hotel and spa, with less of a preference for where it is. In contrast, the husband may prioritize being in the mountains in order to hike but has less of a preference on the accommodations. By recognizing these priorities, the couple can discover mutually beneficial outcomes (i.e., a luxury hotel in the mountains). Because many real-world negotiations tend to involve multiple issues among interdependent parties, we focus in this chapter on integrative negotiations, and in particular, the processes through which negotiation parties can attain high levels of joint gain (i.e., in which both parties' most important interests are satisfied).

Another important variant of negotiations is the social context in which they are embedded. Negotiations can range from involving large multinational teams to occurring within a single person (Raiffa, 1982). They can occur between dyads (e.g., two individuals), teams (e.g., groups made of up more than one individual), organizations, and nations. Negotiation parties can have personal interests at stake in the negotiation or be external brokers (as occurs in representative negotiations). Communication during a negotiation can be done directly or via an external negotiation mediator. Negotiators can also have varying levels of power (control over resources in the negotiation) and status (prestige and esteem). Each one of these contextual variables has important implications for how a negotiation plays out and which negotiation strategies will be more successful. Moreover, contextual effects extend beyond proximal social-contextual negotiation factors to the macroenvironmental context. Indeed, many of these factors are *cultural* in nature and interact with the proximal processes to dramatically affect negotiation dynamics.

Before discussing how culture influences negotiation, we briefly review some key findings on how negotiation psychology and the social context

affect negotiation dynamics. Much of this early literature was primarily culture-bound—it was developed in the West—and culture-blind—it tended to ignore the influence of culture. As we'll see, this has begun to change in recent years as negotiation theory and research have become more global in their scope and reach.

Basic Psychological Processes

Individual-level research on negotiation psychology can be broadly parsed into research on cognition, motivation, and emotion. Early research on cognition in negotiation took a largely prescriptive approach to studying negotiation, using models of rational decision making to outline best practices during negotiation (Luce & Raiffa, 1957; Raiffa, 1982). However, a more descriptive tradition in negotiation research—wherein people study how negotiators actually behave rather than how they should behave—has grown out of research by March and Simon (1958), Tversky and Kahneman (1973), and Bazerman and Neale (1986), among others.

Research on negotiation and cognition has since documented the effects of negotiation framing (Bazerman, Magliozzi, & Neale, 1985), anchoring and first offers (Kristensen & Gärling, 1997; Northcraft & Neale, 1987; Tversky & Kahneman, 1974; Whyte & Sebenius, 1997), and the availability heuristic (Borgida & Nisbett, 1977). For example, negotiators are much more competitive when issues are framed as losses rather than gains, and first offers have a large impact on final agreements, particularly in distributive negotiations (see Gelfand, Fulmer, & Severance, 2010, for a review). Other literature has emerged on social perception biases, such as the fixed-pie bias, wherein negotiators assume their partner to have interests that are diametrically opposite to their own (Bazerman & Samuelson, 1983; Pruitt, 1981; Pruitt & Lewis, 1975), or reactive devaluation, wherein negotiators discount concessions made by others, assuming that “If it is good for them, it must be bad for me” (Molm, Peterson, & Takahashi, 2003; L. Ross & Ward, 1995). More recent research has also examined relational biases. Some of these studies have examined relational biases in how people search for conegotiators, such that people favor those with whom they have had previously positive experiences (Reb, 2010), whereas others have

documented how people hold biased expectations for negotiating teammates, predicting that ingroup negotiators will perform better than outgroup negotiators (Lewis, 2011).

In addition to negotiator cognition, many studies have examined the impact of negotiators' motivation on processes and outcomes. Some of this research has explored how competitive and cooperative motivation shapes negotiation behavior. Messick and McClintock (1968) advanced four fundamental social motives—altruistic, cooperative, individualistic, and competitive—relating to negotiators' outcome goals for themselves and their partners. These divisions have evolved into a distinction between prosocial (altruistic or cooperative) and proself (individualistic or competitive) negotiators, which reliably predicts negotiation tactics and outcomes (see De Dreu, Beersma, Steinel, & Van Kleef, 2007, for a review). The behavioral and cognitive correlates of proself and prosocial negotiation even extend to teams of negotiators (Beersma & De Dreu, 1999, 2002). Amongst both individuals and teams, prosocial negotiators achieve better joint outcomes than proself negotiators, are better problem solvers, and are less contentious (see De Dreu, Weingart, & Kwon, 2000, for a meta-analysis). Proself and prosocial motivations also extend to how minority and majority groups within a larger team interact in negotiations when they have opposing interests. For example, Velden, Beersma, and De Dreu (2007) found that in negotiations that required unanimous agreement, proself minorities blocked agreements and hurt the entire group, while in negotiations that required majority agreement, proself majority members coalesced together to advance agreements at the expense of minority interests.

Aside from their tendency to cooperate and compete, negotiators may also vary in their *epistemic* motivations. For instance, negotiators who have a high need for cognitive closure (NFC) will “seize” and “freeze” on initial positions in the negotiation, which prevents them from negotiating integrative solutions (De Dreu, Koole, & Oldersma, 1999). NFC may be conceptualized as varying not only across negotiators but also within the same person as a function of time pressure, fatigue, or other forms of mental depletion (Webster & Kruglanski, 1994). Research has crossed NFC with social motivation to produce a four-cell conception of negotiators as either prosocial or proself, and either misers (who are high on NFC) or thinkers (who are low on NFC). De Dreu, Beersma, Stroebe, and Euwema (2006)

used this taxonomy and found that negotiators who were high in epistemic motivation (low in NFC) and had prosocial motivations engaged in the best problem solving and achieved the highest joint outcomes.

Research on negotiator behavior has also considered emotion, most often as a predictor of negotiation processes and outcomes, although there is a considerable body of work on emotion as an outcome of negotiation (Barry & Oliver, 1996). Positive mood during negotiations increases people's willingness to cooperate (Forgas, 1998) and improves their joint outcomes in negotiations that require creative solutions (Carnevale & Isen, 1986). Positive mood facilitates not only trust but also reliance on heuristics, less systematic processing of information, and overconfidence (Kramer, Newton, & Pommerenke, 1993). The effects of positive emotion overlap considerably with those of anger—both lead to more heuristic-based information processing and less cautiousness (Van Kleef, De Dreu, & Manstead, 2004)—in part because both are high-arousal emotions (Andrade & Ariely, 2009). Anger's effect on joint outcomes appears to be contingent on a number of factors. Expressing anger can be beneficial for eliciting concessions when the negotiator has higher power than his or her counterpart (Overbeck, Neale, & Govan, 2010; Van Dijk, Van Kleef, Steinel, & Van Beest, 2008), when the counterpart views a negotiator's expression of anger to be justified (Van Kleef & Côté, 2007), or when anger takes the form of “venting” negative emotion that would otherwise be passively expressed (Fischer & Roseman, 2007). These benefits notwithstanding, negative emotions in general tend to damage the relationship between negotiators (Allred, Mallozzi, Matsui, & Raia, 1997) and to reduce the likelihood of one's negotiating counterpart honoring an agreement (Forgas, 1998). This research on emotion is critical for understanding how negotiations vary across contexts that elicit different emotions. For instance, negotiations that occur over disputes might lead to more negative emotion and anger, while those that occur over deal making might involve more positive affect and happiness.

Social-Contextual Factors in Negotiation

Beyond individual psychological factors in negotiation, research has examined how social-contextual factors affect negotiation dynamics,

including power and negotiation relationships (e.g., dyadic negotiations, teams, representative negotiations, and mediation).

Power

Power represents a person's control over resources (Galinsky, Gruenfeld, & Magee, 2003). Power may be operationalized in many ways, but a common operationalization of power in negotiation research is via negotiators' best alternative to the negotiated agreement, or BATNA. Since negotiators with higher BATNAs can more easily afford to leave the negotiation, they have more power than negotiators who are dependent on the negotiation's success.

Research on power and negotiation has shown that, compared to negotiators with low power, negotiators with higher power have greater overconfidence (Fast, Sivanathan, Mayer, & Galinsky, 2012), more aggressive opening offers (Magee, Galinsky, & Gruenfeld, 2007), lower empathy toward a counterpart (Galinsky, Magee, Inesi, & Gruenfeld, 2006), and greater competitiveness in team negotiations (Howard, Gardner, & Thompson, 2007). Moreover, unequal power is negatively associated with cooperation (Komorita & Barnes, 1969; Sivanathan & Galinsky, 2007) and integrative deal making (Mannix & Neale, 1993; McAlister, Bazerman, & Fader, 1986; Wolfe & McGinn, 2005).

Negotiation Relationships

Negotiations inherently involve more than one individual and therefore exist in a relational context. Negotiations may be dyadic—existing between two individuals—or take place between teams of people, wherein within-team and between-team dynamics affect negotiation agreements. Negotiations may also be conducted through representatives (commonly referred to as “boundary role players”; Adams, 1976), and negotiation coalitions may be formed during multiparty negotiations when certain parties (teams, individuals, or both) come together to negotiate as a unit against another coalition. These relational dynamics are discussed in the following two sections.

Dyads

Relational dynamics between dyadic negotiators has been a topic of both classic and recent research. Classic social-psychological experiments show that identification with an ingroup fosters cooperation with fellow members and hostility toward outgroup individuals. Kramer (1991) and Polzer, Neale, and Glenn (1993), who extended these findings to negotiations, found that negotiators are more likely to share information with ingroup members (friends they had brought to the study) compared to outgroup members (strangers whom they met for the first time during the study). Negotiators also appear more likely to cooperate when they expect future interactions with their negotiating partners (Gruder, 1971; Pruitt & Carnevale, 1993). They are also more likely to care about distributive outcomes when negotiating with someone with whom they have a negative relationship, and more likely to care about integrative outcomes when negotiating with someone with whom they have a positive relationship (Drolet, Larrick, & Morris, 1998).

Other early literature focused on how negotiation dynamics shift, based on the relational closeness of negotiating partners. Lamm and Schwinger (1980) found that people are more likely to consider the needs of their counterpart when negotiating with friends versus strangers, and O'Connell (1984) found that friends are more tolerant of unbalanced negotiation exchanges than are strangers. Other studies, however, have documented drawbacks to friendship-based negotiations. Thompson, Peterson, and Brodt (1996) found that teams of friends make less accurate judgments and reach fewer integrative agreements than do teams of strangers, and Fry, Firestone, and Williams (1983) found that dyads composed of strangers had higher aspirations and more frequently exchanged information pertinent to the negotiation, even though friends exchanged more total information. Gelfand, Major, Raver, Nishii, and O'Brien (2006) provided a theoretical synthesis of this literature, arguing that negotiators who have a relational self-construal may engage in relational satisficing and fail to achieve optimal economic agreements even though they attain high relational capital. More recent research has explored the conditions under which preexisting relationships might not be detrimental. Kray, Thompson, and Lind (2005) examined the joint effect of accountability to outside individuals and

preexisting negotiation relationships on the realization of mutually beneficial agreements. Their results showed that negotiators who had a previous relationship were more likely to reach agreement under conditions of high (vs. low) accountability, whereas strangers were more likely to reach agreement under low accountability.

Teams

Research also shows that negotiations vary dramatically depending on whether they occur in teams (two or more people in each party) or between individuals. Generally speaking, team negotiations are more effective than individual negotiations (Morgan & Tindale, 2002; Thompson et al., 1996). Teams generally have greater expertise (Hill, 1982; Kaplan, 1987), greater problem-solving ability (Brodt & Dietz, 1999; Hastie, 1986), and greater diversity of opinions with which to understand a problem (Hastie, 1986; Hill, 1982). Teams also have greater goal commitment and greater accountability than their solo counterparts (Brodt & Thompson, 2001) and a greater repertoire of strategies at their disposal (Brodt & Tuchinsky, 2000). However, negotiating in teams also has drawbacks. Teams often take longer to reach agreements, particularly as the number of issues increases (Rubin & Brown, 1975). Team negotiations (among Western negotiators) are often more competitive than individual negotiations, as teams are often greedier than individuals (Wildschut, Pinter, Vevea, Insko, & Schopler, 2003). Other key variables moderate team efficacy: Specifically, groups are most effective when members are highly identified (Eggins, Haslam, & Reynolds, 2002) and have high relationship quality (Keenan & Carnevale, 1989). Powerful teams are also especially competitive (Howard et al., 2007).

Negotiations often take place between *representatives* of different teams, departments, organizations, or nations. These representatives operate in different circumstances than do typical negotiators, with a unique set of challenges (Gelfand & Realo, 1999). Adams's (1976) boundary role model of group representation explains how representatives must take on different roles when dealing with people inside and outside of their groups. For example, diplomats are accountable not only to their country's government but also to parties of an international negotiation, and it can be challenging

to balance these roles. Often, constituents urge representatives to distance themselves from the other group and be as competitive as possible, which can impair representatives' negotiation effectiveness (Benton & Druckman, 1974; Gruder, 1971). Constituents may also have unrealistic aspirations about negotiation outcomes, which can lead to unfair dissatisfaction toward representatives (Wall, 1975). Moreover, accountability increases representatives' toughness and competitiveness in Western negotiation contexts, and motivates representatives to gain approval from their constituents, often resulting in suboptimal outcomes. In one study by Benton and Druckman (1974), for example, accountable representatives behaved similarly to representatives who were given competitive instructions—setting equally competitive goals and rejecting offers at a similar rate. The best joint negotiation outcomes often happen when negotiators are not only accountable but also have some encouragement to reach integrative agreements (Carnevale et al., 1981). Other research has studied the selection of representatives. For example, Teixeira, Demoulin, and Yzerbyt (2011) found that groups are more likely to prefer external representatives for negotiations about material goods, since external representatives may have more knowledge about outgroups and also be able to exert more leverage on outgroup counterparts. However, groups prefer internal and normative negotiators (e.g., someone who matches the group stereotype) for more symbolic negotiations (e.g., Israel–Palestine negotiations over land) since normative negotiators are seen as better suited to advance ingroup goals.

Third Parties

Another important contextual factor in negotiation is the presence of a mediator. Negotiators can feature a mediator either because disputes cannot be solved by the original parties or because of formal mediation norms in a culture (Rubin & Brown, 1975). Mediators serve an array of functions in a negotiation, ranging from facilitating communication, identifying alternative solutions, reinforcing and establishing procedural norms, and resolving disputes between negotiators (D. Johnson & Tullar, 1972; Kerr, 1954). To accomplish these goals, mediators have been found to use rewards

and threats (Carnevale & Peggnetter, 1985; Rubin & Brown, 1975), to share information (Touval & Zartman, 1965), and to manipulate the context (e.g., through humor) to facilitate negotiation success (Kressel & Pruitt, 1989). In general, negotiations that have mediators feature greater agreement (Deutsch & Krauss, 1965; D. Johnson & Tullar, 1972; Kerr, 1954) and less reactive devaluation (W. Ross, Conlon, & Lind, 1990), although mediated agreements are sometimes seen as less fair than those reached by independent negotiators.

CULTURE AND NEGOTIATION

Culture has been shaping negotiation processes for thousands of years. The Ancient Greek Historian Herodotus described crucial negotiation breakdowns between Persian and Greek empires, whereas Tacitus illustrated the frustrations of intercultural peace negotiation as Rome and Germanic groups were repeatedly brought into conflict. Hundreds of years later, similar breakdowns occurred between Native Americans and Western settlers, and between Maori natives and British settlers in New Zealand, with the latter resulting in the exploitative Treaty of Waitangi.

In each of these historical cases, cultural factors proved an insurmountable obstacle to effective negotiation. Each cultural breakdown came at the cost of lives, land, and group sovereignty, making these cases unambiguously important topics of study. Nevertheless, scholarly work on negotiation and culture has a surprisingly brief research history. Until about 50 years ago, culture had been entirely neglected by scholars of organizational behavior and early articles on culture and negotiation (Porat, 1970; Shapira & Bass, 1975) often identified cross-cultural differences in negotiation strategies, without explaining the specific elements of culture that accounted for such differences or the theoretical implications of these differences (see Gelfand, Erez, & Aycan, 2007).

With the arrival of cultural taxonomies such as Hofstede's (1980) set of cultural value dimensions, researchers began documenting how dimensions such as individualism–collectivism (Bangert & Pirzada, 1992; Tse, Francis, & Walls, 1994), power distance (Bangert & Pirzada, 1992; Graham, Mintu, & Rodgers, 1994), and uncertainty avoidance (Bangert & Pirzada, 1992;

Natlandsmyr & Rognes, 1995) affected negotiation strategies. However, such studies were still rare in the 20th century, and they remained largely descriptive—reaffirming cultural differences along particular dimensions rather than tracking *why* these dimensions were especially relevant to the negotiation process, or how they could be moderated by other factors. While reviewing this research, Gelfand and Dyer (2000) identified three systematic limitations in scholarly considerations of culture and negotiation. First, many authors equated culture with nationality. Second, research often neglected the psychological *processes* involved in negotiation. Third, research had predominantly treated culture as a main effect influencing negotiation outcomes, rather than a moderator.

In the last 15 years, however, organizational behavior has developed a much-needed focus on culture (Gelfand et al., 2007). This wave of cultural research has allowed for the theoretical evolution of cultural taxonomies (Gelfand et al., 2011b; House, Hanges, Javidan, Dorfman, & Gupta, 2004; Leung & Bond, 2004; Schwartz, 1994; Smith, 2006) and has facilitated greater attention to how culture interacts with context to affect negotiation outcomes (Ayman, 2000; Gelfand et al., 2013; Salili, Chiu, & Lai, 2001). This new research has also considered the influence of emic factors, culture-specific ideas that can be contrasted with culture-general or universal dimensions (Berry, 1969; Morris, Leung, Ames, & Lickel, 1999). The result is a new theoretical focus on how culture influences negotiation, with a process orientation and sensitivity to contextual factors.

In the following sections, we review this work, highlighting key ways in which culture affects negotiation dynamics and outcomes. In this review, we highlight how culture has both direct and moderating effects on negotiation dynamics and outcomes. We also differentiate between the way culture affects deal making (e.g., when parties are trying to form a deal) and disputing (when parties have a rejected claim), and how dynamics vary in intracultural and intercultural negotiations. We conclude with a discussion of culture and third parties.

Culture and Psychological Factors in Negotiation

A significant amount of the research on culture and negotiation has addressed how culture shapes the negotiating individuals' cognition, motivation, and emotion. This research has identified not only universal cross-cultural tendencies but also important cultural differences.

Culture and Negotiator Cognition

There is now mounting evidence that negotiators' biases and cognitive frames vary critically across cultures. In one illustrative study, Gelfand and colleagues (2001) asked Japanese and American participants to sort different negotiation conflict episodes and then used multidimensional scaling (MDS) to identify the dimensions on which individuals evaluated the conflicts. The MDS results illustrated that there were some universal dimensions that both Japanese and Americans used to evaluate the conflicts. For example, participants in both cultures differentiated conflicts based on whether one party was trying to "win" or whether both parties were trying to compromise. However, even within this universal dimension, Japanese rated more conflicts to be about compromise than winning as compared to Americans. Moreover, other dimensions emerged that were unique to each cultural group. Americans perceived conflicts in terms of how much they infringed on personal interests and autonomy, whereas Japanese perceived the same conflicts in terms of how much they violated duties and obligations (termed *giri* in Japanese). This study illustrated that people from different cultures not only value different elements of negotiation, but they also approach negotiation with fundamentally different cognitive representations of what is being negotiated.

Research has also shown that biases in negotiation are subject to cultural variability. For example, Gelfand and Christakopoulou (1999) found that Greeks (from a collectivist culture) were significantly less susceptible to the fixed-pie bias—the tendency to see negotiation outcomes as purely win-or-lose—compared to Americans (from an individualist culture) in intercultural negotiations between the two. Gelfand and colleagues (2013) found that collectivists were also less susceptible to self-enhancing biases compared to individualists. Common attribution errors during negotiations also appear to be culture-specific. Whereas research with American subjects

revealed that people overattribute negotiation outcomes to partners' personalities (Morris, Larrick, & Su, 1999), subsequent cross-cultural research found that this bias was larger in American than in East Asian participants (Morris, Leung, & Iyengar, 2004). Negotiators' expectations of their partner's trustworthiness also tend to vary across cultures. In one study, for instance, Gunia, Brett, Nandkeolyar, and Kamdar (2011) found that Indian negotiators had significantly lower expectations of trust from a negotiation compared to American negotiators.

Some cognitive biases, most notably those that stem from information availability, have shown universal effects. For example, negotiators in Thailand display the same anchoring bias around first offers that have been identified in Western negotiators (Gunia, Swaab, Sivanathan, & Galinsky, 2013), though W. Adair, Weingart, and Brett (2007) found that early offers facilitated information sharing and ultimately high joint gains in Japan but caused anchoring and lower joint gains in the United States. The authors explained this finding by theorizing that Americans interpreted early offers as attempts to leverage strong claims, whereas Japanese negotiators were more likely to interpret early offers as attempts to convey interests and priorities. Other research has reproduced framing (Kühberger, 1998) and availability (Hunter & Schmidt, 2004) heuristics in multiple cultures.

Many cross-cultural studies have documented cultural differences in analytic versus holistic cognitive styles, which also have implications for negotiation strategies. People in East Asian cultures with relatively high interdependent self-construal tend to use a more holistic cognitive style (Nisbett, Peng, Choi, & Norenzayan, 2001). These differences in cognitive style also have significant consequences for other decision biases that are relevant to negotiation. For example, Liang, Kale, and Cherian (2014) found that Chinese participants are more likely than Americans to escalate in their commitment to a failing product in which they have already invested, showing more susceptibility to the sunk cost fallacy. To explain this finding, the authors speculated that analytic thinkers might see trends more linearly than holistic thinkers, which means that analytic Western thinkers may be more likely to believe that a failing venture will continue failing (see also Maddux & Yuki, 2006). While the authors did not directly test which cultural factors mediated these effects, they did find that Chinese participants identified more potential causes for problem performance, and

more contextual information—defined as information that wasn't directly tied to the product's previous performance—when justifying their decisions. These trends suggest that Chinese participants' higher belief in dialecticism could have driven their escalation of commitment. An alternative explanation, however, could be that Chinese participants had greater motivation to save face, prompting them to continue supporting a failing product (see Brockner et al., 1982). These different explanations provide an interesting topic for future research. Furthermore, while this study didn't examine escalation of commitment in the context of negotiations, it suggests that East Asian negotiators might also be more likely than Western negotiators to persist in failing negotiations.

Culture and Negotiator Motivation

People across cultures vary not only in how they cognitively process events in a negotiation but also in their fundamental motivates during a negotiation. East Asian negotiators and Middle Easterners generally place greater emphasis on relational outcomes than do Western negotiators (Gelfand et al., 2013; Oetzel et al., 2001), and Western negotiators focus more on economic outcomes. These differences are “rational” when considering the ecology of different negotiation contexts. In Asian and Middle East cultures, relational mobility is lower, social network ties are denser, and individuals are more concerned with saving face (Morris, Podolny, & Ariel, 2000). Negotiators in these cultures tend to be more focused on preserving the relationship with their negotiating partner. In individualistic cultures, where there is high relational mobility, weaker ties, and face is less of a concern, negotiators tend to focus on instrumental motivation, and “getting to yes” as quickly and efficiently as possible.

These structural differences produce highly divergent foci in negotiations. On the one hand, they imply that negotiators in the West are more likely to intuitively trust strangers (see Rand, Greene, & Nowak, 2012) than are negotiators in Asia and the Middle East, who make larger distinctions between ingroup and outgroups members (Fulmer & Gelfand, 2015; Triandis et al., 2001; see also Ma, 2010). Indeed, American negotiators appear to show more trust than Indian (Gunia et al., 2011), and Middle

Eastern negotiators, who are more likely to be concerned about the possibility of betrayal from strangers (Bohnet, Herrmann, & Zeckhauser, 2010; see also Kong, Dirks, & Ferrin, 2014). The exact mediators for these effects have yet to be explored, but we suspect that in cultures where network ties are weak and there is high mobility (e.g., where people interact with different people on a regular basis), it is easier to develop “swift trust” as compared to contexts in which network ties are strong and there is low mobility (e.g., when one rarely interacts with people outside of the network). Strong ties and low mobility also enable mutual monitoring that sustains trust and cooperation in collectivistic cultures, which can produce less trust in anonymous interactions with strangers (Mifune, Hashimoto, & Yamagishi, 2010; Yamagishi, 1998). Accordingly, it is not surprising that trust in strangers is lower in East Asian and Middle Eastern contexts.

However, Western negotiators’ tendency to swiftly seek out trust and agreement can sometimes be a drawback. For example, Americans often set unrealistic expectations for how quickly negotiations will be resolved, which negatively influences the quality of their outcomes. Salmon and colleagues (2016) found that American participants—as compared to Lebanese participants—saw time as relatively more condensed (i.e., tended to overestimate the passage of time), made more concessions, and achieved lower negotiation outcomes as a function of these perceptions. Westerners’ reliance on rational strategies may also cost them in Middle Eastern contexts, where honor preservation is a salient motivation (S. Cross et al., 2014; Uskul, Cross, Sunbay, Gercek-Swing, & Ataca, 2012). Indeed, using a newly developed honor dictionary, Gelfand et al. (2015) found that while rational language was positively related to high joint outcomes in American negotiations, it was negatively related to joint outcomes in Egypt. By contrast, negotiators using honor language achieved higher joint outcomes in Middle Eastern negotiations (see also Aslani et al., 2016).

Culture and Negotiator Emotion

Negotiation researchers seldom study culture and emotion together, but there is a growing body of work with direct relevance to the role of emotion in culture and negotiation. Much of the research that most directly ties

emotion to cultural differences on negotiation has focused on the role of anger. In everyday life, expressions of anger are typically inappropriate and culturally proscribed. In this sense, one might expect angry negotiators to be less successful than nonangry negotiators. However, research on culture and anger has revealed a much subtler role of anger in negotiation, depending on who is expressing anger, who is perceiving anger, and the cultural context of the negotiation. Adam, Shirako, and Maddux (2010) examined how negotiators *perceive* anger in negotiations in different cultures. Their research was inspired by communication breakdowns between the United States and Japan, in which President Bill Clinton's angry negotiating style elicited hostility and blocked cooperative channels with Prime Minister Morihiro Hosokawa. The authors studied how Japanese and American negotiators responded to a counterpart's anger and found that both Japanese and American negotiators conceded equally and highly when their counterpart's anger was appropriate given the context. However, when anger was contextually inappropriate, Japanese negotiators conceded less than did Americans, showing greater reactance to their counterparts' non-normative behavior.

In other research, Adam and Shirako (2013) have studied how culture interacts with *who expresses* anger. In their studies, expressors of anger in a negotiation were manipulated to be either European American or East Asian. Results showed that negotiators—regardless of their own nationality—conceded more when faced with an angry East Asian negotiator, but only when participants had a stereotype of East Asians as emotionally inexpressive. The authors suggested that this pattern occurred because East Asian anger stood out more than did European American anger, leading to perceptions of angry East Asian negotiators as tougher. Future research should also consider the role of status in how anger affects negotiations in different cultures. Whereas anger in the West is typically used more by lower-status individuals as an expression of frustration, East Asians are more likely to use anger as a demonstration of power and authority (Park et al., 2013), meaning that status might moderate how anger is both perceived and expressed in East Asian versus Western cultures.

Studies by Fulmer, Gelfand, Van Kleef, and Adam (2018) moved beyond culture and anger to investigate how people from different cultures perceive pride and shame during negotiations. They found that East Asians conceded

more when they negotiated with East Asian partners who expressed shame compared to pride. In contrast, European Americans conceded more when they negotiated with East Asian partners who expressed pride compared to shame. Interestingly, neither group was affected by the emotional expression of European Americans. These effects underscore the importance of considering both the perceiver and the perceived person in studies on culture and negotiation.

Other research has considered the how anxiety and humility influence cultural differences in negotiation. In dispute negotiations, Chinese negotiators report more anxiety and uncertainty during negotiation than do Dutch negotiators, who report more irritation and less friendliness than do Chinese negotiators (Kopelman & Rosette, 2008). In a follow-up study, Chinese negotiators also showed less overt negative emotion than did Israeli negotiators. These differences can be interpreted as largely strategic on the part of the negotiator, since humility (which involves minimizing disagreement and arrogance) is a more effective means of winning concessions in an East Asian cultural context than in a European cultural context (Kopelman & Rosette, 2008).

Culture and Negotiation Strategy

Beyond research on culture and cognition, emotion, and motivation, research has shown that people use very different strategies throughout the negotiation across cultures in both deal-making and disputing contexts, which we discuss next.

Culture and Strategy in Deal-Making Negotiations

Research on culture and deal making has identified two predominant strategies that negotiators use (Brett, 2007). These include information exchange around one's interests and priorities, and persuasion and offers that are communicated either directly or indirectly (Gunia et al., 2011; M. Liu & Wilson, 2011). Information sharing generally tends to promote value creation (more integrative deals that benefit both negotiators), whereas persuasion and offers promote values claiming (deals that benefit one

negotiator at the expense of his or her counterpart; Kong et al., 2014). However, people's preferred strategies vary critically based on culture. Western negotiators are more likely to employ information exchange strategies than Easterners, while Eastern negotiators tend to prefer persuasion and indirect offer negotiation. Indeed, different strategies lead to high joint gain in different cultures: Using direct information exchange leads to higher negotiation outcomes in the United States, but using more indirect strategies leads to higher outcomes in Asia (W. Adair, Okumura, & Brett, 2001).

More recently, scholars have pointed to the role of trust in explaining these differences in negotiation strategies. For instance, Gunia and colleagues (2011) found that Indian negotiators' lack of trust inhibits their ability to seek out integrative outcomes and compromise positions, compared to Americans. This difference may occur because trust is critical to information exchange in negotiation (Lügger, Geiger, Neun, & Backhaus, 2015), and as mentioned earlier, Americans' higher trust allows them to seek out negotiation trade-offs (Ferrin & Gillespie, 2010; N. Johnson & Mislin, 2012). Another potential factor in cultural strategy differences might be descriptive norms. Confucian values and other East Asian ideologies tend to emphasize harmony and deemphasize explicit conflict. This ideological difference might explain East Asians' tendency to use indirect modes of communicating in deal-making negotiations rather than frankly present information regarding their personal interest.

This latter perspective is supported by research on the means by which Eastern and Western cultures compete in negotiations. Western negotiators, for instance, tactically use expressions of anger (Severance et al., 2013) and are more likely to engage in direct confrontation than Eastern negotiators (Brett, 2007; Zhang, Liu, & Liu, 2014). While Eastern negotiators also value competition in negotiation (M. Liu & Wilson, 2011), they display it more indirectly. For example, East Asian negotiators take up more physical space at the negotiation table (Semnani-Azad & Adair, 2011) and manipulate negotiations by selectively sharing information (M. Liu, 2009, 2011). Given that effective negotiators must employ at least a modicum of competition given the mixed-motive nature of this context, it is not surprising that negotiators of all cultures make use of competitive strategies. The means by

which they do so, however, offer insight into the nature of descriptive norms across cultures.

Culture and Strategy in Disputing Negotiations

Research on culture and disputing negotiations has largely focused on the cross-cultural limitations of the rational actor model. Decades of prior negotiation research approached dispute negotiations with the assumption that delegates tasked with resolving political violence made rational choices. This model of negotiation proved effective at analyzing Cold War era negotiations, yet it was largely irrelevant for conflict resolution efforts in Middle Eastern countries. To expand the rational actor model, Atran, Axelrod, and Davis (2007) proposed a “devoted actor” model derived from negotiations that involved sacred values. This model was developed with sensitivity to the Israel–Palestine dispute, in which negotiators had practiced irrational strategies in which they had rejected resource-rich deals and rationally favorable trade-offs. To explain these decisions, the authors argue that concessions that might seem rational to Westerners, such as a land-for-money exchange, infringe on the sacred values of parties in an ongoing conflict, as in the conflict between Israel and Palestine. In follow-up work, Atran and Axelrod (2008) offered strategies for negotiations that involve sacred values, such as assuring protection of sacred values at the beginning of negotiations rather than the end, and refraining from offering material goods (e.g., money) in exchange for something sacred, such as ancestral land.

More recent research has explored the origins of sacred values in negotiations and has suggested new means through which negotiators can resolve disputes that involve sacred values. Atran and Ginges (2012), for example, attribute cultural differences in sacred values to the evolution of religious systems. Organized religious systems may have evolved in part because they foster cohesion and strong ingroup norms through the prevalence of large-scale rituals and costly signaling—sacrificing that signals commitment to an ingroup (Atran & Norenzayan, 2004; Henrich, 2009). Atran and Ginges (2012) argue that these elements of various religious traditions fostered cultures of high moralization, wherein pragmatic areas of

cultural decision making (land ownership) take on sacred meaning (Atran & Norenzayan, 2004). As a function of these strong ingroup norms, however, religious cultures can sometimes show greater hostility toward outgroups, including more prevalent warfare and violent extremism (Sosis, Kress, & Boster, 2007). In this sense, religion's emphasis on sacred values does not fit well with dominant rational models of negotiation. Further work is needed on how religion can be conceptualized in the negotiation process, and how secular negotiators can best negotiate with counterparts whose decision making is affected by religious values.

Honor is another important component of decision making among devoted actors. Recent work has explored the evolutionary determinants of Middle Eastern honor cultures, and how honor cultures influence negotiation decision making. One agent-based model on this subject found that environments with unstable institutions cultivate the emergence of honor cultures (Nowak, Gelfand, Borkowski, Cohen, & Hernandez, 2016), building on classic work in social psychology indicating that ecological differences between the U.S. South and North led to a Southern "culture of honor" (Nisbett & Cohen, 1996). In environments with inadequate law enforcement, individuals need to protect themselves, and they need to maintain a reputation for toughness, so that others do not take advantage of them. This may be why symbolic concessions hold so much value for Middle Eastern negotiators and it also suggests discrete strategies with which Western negotiators might effectively resolve conflicts in the Middle East, such as explicitly recognizing the importance of sacred values at the beginning of negotiations.

Culture and Context in Negotiation

Until now, in this chapter we have considered cultural differences in negotiation somewhat generally, without consideration of how these cultural differences might be moderated by an array of factors. Indeed, this limitation is inherent to much research on culture and negotiation, and only in the past 5–10 years have scholars begun to identify the elements of negotiation that amplify or reduce cultural differences in psychological or social negotiation processes. This emerging literature takes a *culture-by-*

context approach to understanding the role of culture in negotiation (Gelfand et al., 2013).

Some contextual moderators of cultural differences are structural. For example, accountability tends to increase culturally normative behavior, as negotiators feel accountable to others within their culture. Whereas early researchers of negotiation and accountability had presumed that accountability increases negotiators' competition, these studies had only been done with Western samples, in which negotiation norms are largely competitive. In innovative work, Gelfand and Realo (1999) showed that accountability amplifies normative tendencies. It makes interdependent people more cooperative (Gelfand & Realo, 1999) and those from collectivist cultures more relational in their negotiation goals—but only when negotiating with an ingroup member, such as someone from their own company (W. Liu, Friedman, & Hong, 2012). Accountability therefore leads people to conform more to cultural norms and scripts (Gelfand, Nishii, & Raver, 2006; Yamagishi, Hashimoto, & Schug, 2008), and in doing so may amplify cross-cultural differences.

Gelfand and colleagues (2013) found that these contextual moderators of culture could also influence cross-cultural differences in teams: Specifically, whereas teams outperform solos in negotiations in Western cultures (Thompson et al., 1996), the researchers expected that they would do worse in teams in collectivistic cultures. In particular, they argued that the team context activates cultural norms and amplifies a concern for harmony norms that predominate in collectivistic cultures. They found that Taiwanese negotiators not only showed more motivation toward harmony in team versus solo negotiations, but their motivation toward harmony also led Taiwanese teams to negotiate especially suboptimal joint outcomes (as measured by Pareto efficiency) compared to individuals.

As negotiations more frequently are conducted online, new research on context and culture has explored whether cultural differences translate to virtual negotiations. In the limited research that has been published, it appears that some cross-cultural differences translate virtually. In an e-mail study, German negotiators used more information sharing and fewer influence behaviors than did Chinese negotiators (Lügger et al., 2015), reaffirming previously established cultural differences. However, in another study, participants from Hong Kong expressed more competitive goals in an

e-mail negotiation compared to Western negotiators in an intracultural negotiation (M. Liu & Wilson, 2011; Rosette, Brett, Barsness, & Lytle, 2012). No mechanism was directly tested, but presumably Hong Kong participants felt more emboldened to be competitive when negotiations were not conducted in a face-to-face context. Besides these e-mails studies, however, there has been little research on online negotiation. Particularly when negotiators are less accountable due to the anonymity of their online environment, individuals can obscure personal information and exit negotiations with fewer consequences. This research provides useful insight, however, in that it allows researchers to test whether cross-cultural differences in negotiation styles persist in these less accountable online environments.

Another prominent psychological moderator of cultural differences is the need for cognitive closure—individuals' desire to arrive at definitive conclusions and avoid ambiguity. Cultural differences appear largest among individuals with high cognitive closure and in situations where cognitive closure is highest, such as under time pressure (Chao, Zhang, & Chiu, 2009). Cognitive closure has been shown to moderate a wide range of cultural differences in negotiation, such as differences in conflict orientation, procedural preferences, and information-gathering strategies (Fu et al., 2007). In each case, cognitive closure amplifies established cultural differences. For example, Americans, as compared to Chinese, tend to report higher scores on competitive motivation, and this is increased among negotiators with a high need for closure. This tendency might stem from the fact that high cognitive closure encourages people to rely on cultural scripts as clear guides to behavior, with low ambiguity.

Intercultural Negotiation

Cultural processes in negotiation are shaped by not only structured and psychological moderators but also one's negotiation partner. In an increasingly globalized world, negotiations are often held across cultural groups. These negotiations feature unique *intercultural* effects that stand apart from the *intracultural* effects that we have documented thus far. Furthermore, different cultures can meet across the bargaining table

(intercultural negotiators) or on the same side (multicultural teams). In this section, we review literature from both contexts.

Intercultural Negotiators

By summer 1951, the Korean War had cost tens of thousands of deaths, and over \$6 billion to the Korean economy. Additionally, more than half of Americans who initially agreed with the war had withdrawn their support, and Mao Zedong had lost one of his sons in the conflict. Yet even with these factors—and the fact that all sides sought similar terms—negotiations were drawn out for 2 years. Even when Russia, the United States, and North Korea all agreed on an armistice, China rejected the terms, refusing to trust Western powers. The negotiation's difficulty illustrates how intercultural negotiations can face difficult obstacles, even when they look easily achievable on paper.

Research findings have consistently supported the challenge of intercultural negotiations. One survey indicated that, in general, intercultural negotiations create less value than their intracultural cousins (Brett, 2007; but see Kern, Lee, Aytug, & Brett, 2012), and in one study using intercultural Israeli–Indian participants, negotiators failed to reach an agreement 60% of the time (L. Liu, Friedman, Barry, Gelfand, & Zhang, 2012). The difficulty of intercultural negotiations cannot be traced to any single factor. Indeed, almost any intergroup process suffers from a lack of trust and the inhibiting presence of intergroup bias (Hewstone, Rubin, & Willis, 2002). And negotiation—in which group differences are made salient by opposing motives—are likely to facilitate hostile interactions that make agreements difficult. In this vein, past research has shown that intercultural negotiators often differ in their expression norms (Ekman & Friesen, 1969; Hammer, 2005; Koopmann-Holm & Matsumoto, 2011) and tend to misattribute counterpart behavior in damaging ways (Salmon et al., 2013). Each of these differences is then compounded by cultural stereotypes that frequently damage joint value among intercultural dyads (F. Adair, Taylor, & Tinsley, 2009; Brett, 2007).

Aside from a host of intergroup biases, intercultural negotiators also struggle to reconcile fundamental differences in communication strategies

(Hall, 1976; Hammer, 2005; Ting-Toomey, 1988). Scholars who study negotiation have yet to resolve when intercultural negotiators will adopt their counterpart's strategy and when they will retain their culture-native approach, and several theoretical models have also struggled to account for this issue. The triangle hypothesis, for example, argues that cooperative negotiators abandon their strategy when they face a competitive counterpart (Kelley & Thibaut, 1978). However, Germans negotiating with competitive Chinese counterparts only partially adapt their behavior—showing more distributive behavior but similar levels of integrative behavior compared to when they negotiate with other Germans (Lügger et al., 2015). In this sense, more research is needed to determine when people will adjust their normative negotiation framework due to their counterpart's culture and how intercultural negotiators can best manage their different styles of communication.

Yet, gaps in knowledge notwithstanding, researchers have identified critical moderators of how successful individuals or groups might be in intercultural negotiations. Of these moderators, cultural intelligence seems to be of particular importance, which is unsurprising given that cultural intelligence is associated with better sensitivity to cultural differences and better adaptation to the norms of outgroup cultures (Earley & Ang, 2003; Thomas & Inkson, 2004). In a study of 124 American and East Asian negotiators, Imai and Gelfand (2010) confirmed the important role of cultural intelligence in intercultural negotiations. In their sample, cultural intelligence—measured a week before a negotiation—predicted negotiator's integrative behaviors, which in turn led culturally intelligent negotiators to achieve high joint outcomes. In a more recent study, L. Liu, Ma, Chua, Zhang, and Barzanty (2013) found similar patterns: Chinese and American negotiators achieved higher joint outcomes as a function of their cultural intelligence and were better able to manage their relationship with their negotiating counterpart.

While cultural intelligence is a stable individual difference, discreet behavioral markers may also facilitate effective intercultural communication. In fact, even frequently saying the word *you*—which closes social distance—created value for Korean negotiators with American counterparts (Kern et al., 2012; Yoon & Yang, 2012). Other treatment interventions have also shown promise. Emphasizing relational goals over

task goals produces more informational integration and cultural intelligence—critical elements for effective intercultural negotiations (Ogan, Alevan, Kim, & Jones, 2010; but see Fry et al., 1983), and negotiators who send clear messages (L. Liu, Chua, & Stahl, 2010) and make an effort to take the perspective of their counterpart's culture (Giannetti & Yafeh, 2012) enjoy the best intercultural negotiation joint outcomes. Of course, experience in other cultures is also a significant moderator of intercultural negotiation success, a claim that has been validated among foreign students studying in France, China, and the United States (L. Liu et al., 2013).

There are also clear inhibitory factors for successful intercultural negotiation. One such factor is the need for cognitive closure. Aside from closure's tendency to make negotiators rely more on ingroup cultural norms, it also appears to hinder intercultural negotiation. This inhibition has been documented among Chinese and American negotiators (L. Liu et al., 2012). Among these subjects, a high need for closure prevented participants from switching to new mental models and adjusting their early strategy. Follow-up research indicated that cognitive closure produced a greater fixed-pie bias among intercultural groups, which prevented effective value creation (W. Liu, Liu, & Zhang, 2015).

Negotiating in Multicultural Teams

Many of the same obstacles and solutions that typify standard intercultural negotiations are involved when multicultural (i.e., culturally diverse) teams negotiate. In both forms of intercultural negotiation, effective negotiators share information, adapt their initial strategy, and effectively communicate their interests (Brett, 2007). Moreover, intercultural trust, cultural intelligence, and creativity are critical regardless of whether individuals or teams take part in negotiations (Gassmann, 2001; Rockstuhl & Ng, 2008). However, multicultural teams also face a unique set of challenges. Because multicultural teams often represent the same collective group (e.g., an organization) and have common outcomes they need to attain (e.g., a work product), it is especially important that they communicate effectively, which may be challenging when team members speak different languages and dialects, and follow different sets of descriptive norms (Henderson, 2005).

To help overcome these obstacles, Brett, Behfar, and Kern (2006) suggested four strategies for effective multicultural teamwork. Their first strategy, *adaptation*, involves acknowledging cultural differences and explicitly adapting practices and attitudes to manage these differences without undermining members' identities. Their second strategy, *structural intervention*, involves changing environmental or other structural features (e.g., team size, location) to remove potential sources of conflict. Their third strategy, *managerial intervention*, involves a mutually supported intervention from an executive to help resolve intercultural conflict. And their fourth strategy, *exit*, involves leaving a team in which cultural differences are irreconcilable and disruptive. These strategies vary in their commonness (e.g., exit is a very rare strategy) and their effective across contexts (e.g., managerial intervention must involve a popular and well-respected authority), but they offer a window into how multicultural teams can use communication and organizational support to coordinate effectively during negotiations.

The aforementioned research represents a rich literature on multicultural teams and may be translated to understand how such teams negotiate. However, scholars have rarely explicitly considered multicultural team negotiations, despite the growing rate of multinational corporations and increasing contact between these corporations (Halverson & Tirmizi, 2008). Cultural tightness–looseness—the strength of cultural norms and tolerance for deviant behavior—may also impact how multicultural teams negotiate. Looser cultures are typically more creative and display more openness to outgroup members (Gelfand et al., 2011b), which might foster success in multicultural teams. However, tight norms might be beneficial on the team-level, since it is associated with ingroup trust, coordination, and cohesion (Gelfand, Harrington, & Jackson, 2017b). Furthermore, tightness could help negotiators prioritize shared interests over individual pursuits and through increased self-control (Gelfand et al., 2011b; Harrington & Gelfand, 2014). While these effects are theoretically supported, more research is needed to test their empirical support.

Mediation and Culture

Negotiations has classically been considered to involve two-party interactions, but they very often involve mediating third parties. The last 20 years have seen a flourishing research into third-party negotiations, with particular attention to mediation in which a mediator helps two parties negotiate a deal (Wall & Blum, 1991). Of all the factors that influence mediation, culture has been considered the most powerful and also the most intriguing (Wall & Lynn, 1993).

Culture and the Mediation Process

The importance of culture in studying mediation might be in part because mediation is largely an emic feature of negotiation—its prevalence and nature varies critically across cultures, and mediations feature very few universal elements. Instead, mediated negotiations are idiosyncratically and locally defined. Despite this diversity, mediators in Western and non-Western communities tend hold positions of high responsibility (Wall & Blum, 1991), a claim that has been supported by descriptive reports of negotiations in Sudan, the Philippines, Afghanistan, and Mexico, where mediators are given great power to settle disagreements in a manner than benefits their community at large (Merry, 1982, 1989).

Given that mediators often represent the interests of their home culture in a negotiation, it is not surprising that they display a keen sensitivity to cultural norms. This sensitivity may be most prominent in the mode in which mediators are trained. In China, mediators are often trained to restore harmony in society (Laden, 1988), a mandate that reflects important Confucian ideals (Hofstede & Bond, 1988). American mediators, however, are trained to approach disputes in an unbiased manner and to divide value equally, tactics that are more reflective of traditional democratic ideals (McGillicuddy, Welton, & Pruitt, 1987; Welton & Pruitt, 1987). While each culture's mediation training appears functional in its own right, both clearly derived from cultural norms and values. Moreover, they may produce very different mediation outcomes, depending on the nature of the negotiation.

Aside from the training that mediators receive, scholars have studied styles of mediation in different cultures. This research has drawn from general mediation literature, which previously identified differences between

formulative styles of mediation and *manipulative* styles (Carnevale & Peggnetter, 1985; Kressel & Pruitt, 1989; Wall & Rude, 1985). The former style was often identified in mediators who suggested compromises, solutions, and helped disputants reach agreements (Beardsley, Quinn, Biswas, & Wilkenfeld, 2006; Wilkenfeld, Young, Asal, & Quinn, 2003; Zartman & Touval, 1985), while mediators who use the latter style tend to use power and influence (e.g., threat, reward, punishment) to push negotiating parties toward settlement or push single parties off previously held positions (Beardsley et al., 2006; Wall, Chan-Serafin, & Dunne, 2012).

Studies of culture and mediation have largely identified similar strategies across cultures, while documenting emic elements that are unique to each culture. In a Malaysian community, for example, village leaders not only relied heavily on information gathering and consensus seeking (typical of a formulative style) but also used a unique “meet together” strategy and engaged in shared prayer (Wall & Callister, 1999). In contrast, Thai mediators not only used influence and power tactics typical of the manipulative style, but they also emphasized apology and forgiveness during negotiations in a way that manipulative American mediators did not (Callister & Wall, 2004). Japanese mediators relied on a mix of manipulative and formulative strategies, not only using criticism and assertive communication to guide negotiators, but also listening and sharing information in an effort to formulate deals that met the needs of each negotiator (Callister & Wall, 1997). And Indian mediators were found to dictate concession points and agreements differentially depending on their status in the community, with panchayats (mediational groups) using more assertive strategies than solo village elders (Wall, Arunachalam, & Callister, 2008). Other research has extended the study of mediation to Turkey (Kozan & Ilter, 1994), South Korea (Kim, Wall, Sohn, & Kim, 1993), China (Wall & Blum, 1991), and Gambia (Davidheiser, 2005).

Mediating Intercultural Disputes

Past research has largely focused on mediation as it occurs in other cultures, but mediation is increasingly occurring in intercultural negotiations. This intercultural mediation faces the host of challenges we documented earlier

in this chapter, ranging from general intergroup biases to cultural miscommunications and clashing negotiation strategies (Hall, 1976; Hammer, 2005). Moreover, dispute mediators also face unique challenges, such as the outright rejection of their efforts. Analyses of historical dispute mediations revealed that when negotiations involved more cultural distance (were separated further by region, practice, etc.), negotiating groups were less likely to accept a mediator, even though the mediator's efficacy did not ultimately vary depending on cultural distance when the groups did accept mediation (Inman, Kishi, Wilkenfeld, Gelfand, & Salmon, 2014).

When mediators are accepted, their strategy can critically influence the success of intercultural negotiations. Research on disputing negotiations has found that mediators with manipulative strategies are best able to confront challenging intercultural negotiations and generally outperform formulative negotiators (Salmon et al., 2013). The advantage of manipulative strategies is moderated, however, by the difficulty of the negotiation situation. For example, manipulative mediation produced higher-quality agreements in intercultural dyads with more difficult disputants (low openness to mediation and low motivational cultural intelligence, which refer to a low desire to function and manage in culturally diverse situations, low trust, and low willingness to concede), but it produced much lower-quality agreements in dyads with more favorable disputant factors (high openness to mediation, high motivational cultural intelligence, high trust, and high willingness to concede; Salmon et al., 2013).

FUTURE DIRECTIONS

The study of culture and negotiation has had a short history, but it has a promising future. Publication rates indicate that negotiation literature with a cross-cultural focus has increased at an exponential rate over the past 15 years (Gelfand, Aycan, Erez, & Leung, 2017a). Research on culture and negotiation is becoming increasingly more complex, examining how culture interacts with the social context to predict negotiation dynamics, moving beyond intracultural comparisons to include intercultural negotiations, and incorporating emic constructs into theory and research. We conclude with

some promising theoretical and methodological frontiers of culture and negotiation research.

Building More Integrative Theories of Culture and Negotiation

This chapter has examined culture's effect on negotiation cognition, motivation, and emotion as if each process were phenomenologically distinct. Yet each psychological process interrelates as negotiator dynamics unfold at the negotiation table, and we need more coherent conceptual theories that help integrate how culture affects all of these processes simultaneously. Could there be one source of cultural knowledge that explains why Americans shake hands at the beginning of negotiation but are more likely to show overt anger after meeting opposition? We believe that cultural metaphors have the potential to synthesize research on negotiation in general, and culture and negotiation more specifically (Gelfand & McCusker, 2002).

Metaphors are typically thought of as linguistic devices, but conceptual metaphor theory holds that they are more deeply rooted conceptual frames that enable us to make meaning of abstract targets by mapping them to concrete sources (Lakoff & Johnson, 2008; Landau, Meier, & Keefer, 2010). For example, people often refer to time in terms of distance ("a deadline approaches"), and emotion as liquid in a container ("anger is bottled up," "rage erupts"). A particularly exciting extension of conceptual metaphor theory has examined cultural metaphors (Kövecses, 2003, 2005). Since culture is largely a meaning framework that offers behavioral scripts and interpretive lenses, it is dependent on metaphors to help make nebulous social concepts (e.g., love, mating partners) interpretable using more accessible sources (an arrow through the heart, fish in the sea). But cultures do not have equally accessible metaphors, because metaphors are derived from repeated experiences. For example, the first person to compare mating partners to fish probably lived near an ocean. Metaphors often reinforce cultural norms and values, and draw from local ecology (Kövecses, 2003, 2005).

Research has yet to systematically examine the role of metaphor in cultural negotiation (Gelfand et al., 2011a), but Gelfand and McCusker's (2002) metaphoric analysis of Japanese and American negotiation styles hints at the explanatory promise of a metaphoric perspective. These authors argue that since negotiation is an especially abstract target, negotiators often rely on cultural metaphoric mappings—often without their conscious awareness—to understand what are they are doing, what scripts are appropriate, and to determine the criteria for success. In the United States, negotiators tend to draw from sports metaphors, because sports are highly accessible in the culture, while in Japan, negotiators often use a household (*ie*) metaphors, given that they provides an extensive domain of experience to which people are exposed. Each of these metaphors clarifies the problems that negotiators face. For example, Americans using a sports metaphor must *win* the negotiation, while Japanese negotiators using the *ie* metaphor must fulfill their roles in the negotiation. Moreover, each metaphor comes with a set of behavioral scripts. Players in a sport leave everything on the field, work as a team, and show good sportsmanship. In contrast, members of a household must respect their elders, downplay conflict, and put the needs of the family ahead of their own interests. And while emotional expression is typical to any competitive sport, an emotional outburst is proscribed in the *ie* metaphor. Thus, conceptual metaphors are useful for understanding why cultures might not only emphasize different elements of the same negotiation but also translate high-level differences in cultural values into the distinct behaviors that cultural negotiators employ. Moreover, metaphors are dynamic—they can change over time and vary based on context—thereby capturing the ever-changing negotiation process that is increasingly being recognized by negotiation scientists.

While theory had been advanced on how metaphors can provide a conceptual bridge to a holistic understanding of culture and negotiation, there is little empirical research on this approach, which provides an open frontier for future work in the field. Metaphors can also provide a training device for helping negotiators understand how their cultural counterparts are mapping the domain of negotiation, thereby increasing negotiators' cultural intelligence.

Emic Social Processes in Negotiation

While social processes have typically been examined as they differ across cultures, many social processes in non-Western countries are culturally unique. For example, the majority of research on negotiator strategies has drawn from the Profile of Organizational Influence Strategies (Kipnis & Schmidt, 1982), which identifies seven general influence strategies that negotiators employ: pressure, integration, exchange, authority, coalition, sanction, blocking. However, research on negotiation in Japan found that these negotiators used additional strategies—such as highlighting the authority of their firm and using role modeling—in addition to the original seven (Rao, Hashimoto, & Rao, 1997). Other research in Hong Kong found negotiators use an additional “good soldier” tactic, in which they conceptualized negotiation success through hard work, as well as an image-management tactic and a personal network tactic, which relied on informal social connections to accomplish negotiation goals (Ralston, Gustafson, Cheung, & Terpstra, 1993).

There is still a scarcity of literature on culturally emic constructs in negotiation, yet some research has shown early promise. For example, the Chinese notion of *guanxi*—represented as the informal connection that implies the reciprocation of favors and trust in Chinese culture (Hall, 1976)—is associated with a negotiation preference for behind-the-scenes tactics rather than information sharing (Chen & Chen, 2004). Another emic construct—the Arab notion of *wasta*—refers to “pulling strings” through an association with someone of higher power and has been associated with asserting influence during negotiation through third parties who are not involved in the negotiation (Khakhar & Rammal, 2013). Finally, according to Gelfand and colleagues (2001), Japanese negotiators can think of negotiation conflicts in terms of *giri* (one’s dutiful obligations), whereas Americans did not use this construct when analyzing negotiation conflict. Studies on these emic constructs help illustrate the value structures behind culturally unique negotiation strategies, but they have also shown that culture-specific notions are to some degree shared across cultures. In one such demonstration, Smith, Huang, Harb, and Torres (2011) found that *guanxi*, *wasta*, and the Brazilian notion of *jeitinho* (using creative solutions to solve unique problems) were endorsed across Lebanese, Brazilian,

Chinese, and British cultures. Future research should continue to broaden the constructs we examine in culture and negotiation research and integrate them with those that come from a Western approach.

Beyond Linear Paradigms: Computational Agents and Computational Models of Negotiation

Negotiation seldom involves a single interaction. Negotiators must often meet continuously—sometimes over the course of months or years—to revise and renegotiate elements of an agreement. Over this time, the relationship between two negotiators becomes just as important as the issues over which they are negotiating, and strategies that might exploit temporary gains could damage this relationship and eventually hinder an effective resolution (Pruitt & Carnevale, 1993). Thus, negotiations are dynamic—potentially changing dramatically in their nature over time—yet they have been historically studied using one-shot paradigms (Gelfand et al., 2011a). This limitation is in large part methodological. Single negotiation agreements are easier to simulate in a laboratory, and common statistical hypothesis testing focuses primarily on one-shot paradigms.

Within the last 5–10 years, however, computational methods have emerged that allow for an effective study of nonlinear negotiation dynamics (Jackson, Rand, Lewis, Norton, & Gray, 2017). Much of this work has emerged through the lens of dynamical systems theory, in which different elements of a system (e.g., an organization or a negotiation) are seen as interconnected and changing over time (Coleman, Vallacher, Nowak, & Bui-Wrzosinska, 2007; Vallacher & Nowak, 1994). For example, a dynamical systems perspective has recently been applied to study how multiple factors cause and exacerbate intractable conflicts, a topic that had previously been studied as the linear result of single predictors, such as competition over resources (Vallacher, Coleman, Nowak, & Bui-Wrzosinska, 2010). Other papers have applied simulations of computational “agents” to study culture and reciprocity in negotiation (Haim, Gal, Gelfand, & Kraus, 2012), culturally adaptive negotiation strategies (Gal, Kraus, Gelfand, Khashan, & Salmon, 2011), individualist and collectivist trade strategies (Hofstede, Jonker, & Verwaart, 2008), and intercultural communication (Paruchuri et

al., 2013). For example, using their model, Hofstede and colleagues' (2008) found that "individualist" agents who focused on personal interests created more efficient and complex networks than "collectivist" agents who focused on maintaining ingroup bonds and harmony. This article showed how the dynamical modeling of individual-level differences in collectivism could lead to the emergence of more complex group-level differences in trade networks.

Diversifying Samples and Methods

Recent analyses of negotiation research show that even research explicitly concerned with culture is geographically constrained (Gelfand et al., 2013). Perhaps out of convenience, these studies draw over half of their samples from one country (the United States), and even the minority of research that is conducted outside of North America and Western Europe tends to occur in East Asia (Gelfand et al., 2017a). Indeed, the East versus West cultural divide has characterized over 40 years of cross-cultural research, with dimensions such as individualism–collectivism and power distance fueling much of the early research on culture and negotiation. However, the field's narrow focus on East versus West dynamics now threatens to limit future research on culture and negotiation. The reality of globalization means that negotiators from all over the world face each other daily, and unless we begin to sample a more culturally diverse set of negotiators, our theoretical models will continue to apply only to a minority of global negotiations. Research is sorely needed on African, Middle Eastern, and South American samples, as well as among biculturals and immigrants.

Methodological innovations could go far to resolve the problem of sample diversity. Some of these innovations should involve neuroscience and physiological tools (e.g., hyperscanning methods in neuroscience, which provide neuroimaging data from the brains of two interacting participants), bypassing any implicit demand in Western scales and translation issues. Moreover, based on the this review, which shows that *context* is a critical moderator of cultural differences, it is critical for negotiation research to be clear on the features of the negotiation context that are being measured and/or manipulated in cross-cultural research. For

example, the nature of one's negotiation counterpart (ingroup or outgroup) is often left unspecified. More attention to context in both theory and research designs will be important for future research. Perhaps most importantly, we need also to replace standard negotiation procedures to be more cross-culturally sensitive. Current multi-issue paradigms—even those that allow for integrative trade-offs—use formats in which individuals volley for points—reflecting a sports metaphor that can encourage competition. Negotiation paradigms also use economic gains and losses as dependent variables, even though previous research has underscored the importance of relational and reputation gains among Middle Easterners and East Asians. Finally, most negotiation paradigms do not capture the dynamics of intercultural negotiations, which involve many intangible qualities that must be communicated and resolved even before the negotiation begins (e.g., where the negotiation takes place, who negotiates, and how many negotiators are present). New cross-culturally sensitive paradigms will help to improve the quality of future research on the cultural psychology of negotiation, and it should be a high priority in the field.

CONCLUSION

How can psychologists help resolve international disputes and maximize the efficiency of global organizational deals? In this chapter, we have argued for the importance of understanding culture's role in negotiation processes. In particular, we have discussed the origins, evolution, limitations, and future directions of studying culture and negotiation. We divided this work by (1) how culture shapes psychological processes, (2) how culture affects social processes and strategies in negotiation, (3) contextual moderators of the effect of culture on negotiation, (4) the dynamics of intercultural negotiation, and (5) cross-cultural conceptions of mediation. Taken together, we recognize a field that, while young, has made tremendous strides in recognizing the cultural impact on diverse negotiation processes and questioning the universal validity of established negotiation findings. Through the wealth of published research on culture and negotiation, we can now analyze historically significant negotiations through a scientific lens

and train negotiators more effectively to make deals and resolve conflict in an increasingly globalized world.

CHAPTER 25

Culture and Consumer Behavior

Sharon Shavitt, Hyewon Cho, and Aaron J. Barnes

Consumer behavior and marketing are global phenomena, and understanding how consumers around the world respond to marketing efforts is a key managerial priority. Accordingly, consumer researchers have produced a burgeoning literature that builds on insights from cross-cultural psychology. Many of the same factors studied in social psychology have been shown to influence consumer judgments and decisions. These shared factors include individualistic and collectivistic, as well as horizontal and vertical cultural orientations, independent and interdependent self-construals, analytic and holistic thinking styles, and power distance. We review these findings and highlight synergies between social and consumer psychology. We also highlight novel variables addressed by cross-cultural consumer research, including brand symbolism, consumer–brand relationships, and price–quality judgments. We conclude with a call for future work that broadens our theorizing and deepens our understanding of how an emphasis on norms and on others' expectations shapes consumer behavior in various cultural contexts.

Should a brand manager invest heavily in tailoring his or her global brand's marketing efforts to the individual countries in which the brand is marketed? If so, how should this tailoring be accomplished? These are questions that confound many multinational firms as they seek to develop and promote successful brands in varied markets. The decisions are high stakes, with billions of dollars on the line. Fortunately, many of the research

insights emerging from cross-cultural psychology can be applied directly to making these decisions effectively.

In this chapter, we review some of the burgeoning literature on cross-cultural consumer behavior. A growing body of research suggests that culture influences consumer perceptions, preferences, and goals in a variety of ways (see Riemer, Shavitt, Koo, & Markus, 2014, for a review). For instance, cultural factors can influence consumer processing strategies (Briley, Wyer, & Li, 2014), shaping consumers' thinking styles (Lalwani & Shavitt, 2013; Monga & John, 2007) and the role of feelings and metacognitive experiences in consumer decision making (Hong & Chang, 2015). Most of the cultural distinctions and categories examined by consumer researchers are familiar to social psychologists, having been based on foundational psychological literature (e.g., Hofstede, 1984, 2001; Markus & Kitayama, 1991; Triandis, 1995). However, new distinctions also show promise for predicting important consumer judgments in the commercial and prosocial spheres (e.g., Torelli & Shavitt, 2010; Winterich & Zhang, 2014). We begin our review with the role of well-established cultural distinctions such as individualism–collectivism, before turning to newer classifications related to the horizontal–vertical distinction and power distance.

INDIVIDUALISM–COLLECTIVISM AND INDEPENDENT–INTERDEPENDENT SELF- CONSTRUALS

The cross-cultural consumer literature is dominated by a focus on independent and interdependent self-construals, or individualistic and collectivistic backgrounds. Here, we consider findings inspired by these broad classifications that are often used to characterize Western versus non-Western consumer contexts.

Cultural distinctions are clearly reflected in the commercial or informational environments that surround consumers. For instance, Miracle (1987) described the distinct “goals” of advertisements in the United States and Japan, and his insights offer implications for understanding persuasion processes. In American ads, he argued, advertisements try to teach

consumers about the brand and its benefits, on the assumption that consumer learning precedes persuasion and purchasing. The focus is therefore on direct communication with the audience. In contrast, Japanese ads try to make friends with consumers, showing them that the company understands them and can be trusted to take care of their needs. The communication is indirect, focusing on the right mood, tone, and aesthetics, as opposed to persuasive arguments.

Because advertisements are cultural artifacts that shed light on cultural processes, numerous studies have systematically analyzed their content. Primarily focusing on cultural differences in individualism–collectivism, these studies documented culturally linked patterns in the prevalence of various types of appeals. In general, they suggested that the prevalence of marketing communications matches the cultural value profile of the societies in which they appear (e.g., Han & Shavitt, 1994; Kim & Markus, 1999); that is, appeals to uniqueness, personal benefits, and hedonism are more prevalent in individualistic societies, whereas appeals to harmony, group benefits, and conformity are more prevalent in collectivistic societies.

For example, an early content analysis (Han & Shavitt, 1994) showed that magazine advertisements in South Korea, a collectivistic society, were generally more focused on interdependence, family well-being, harmony, and ingroup goals than were magazine advertisements in the United States, an individualistic society. However, U.S. ads focused more on independence, individuality, self-improvement, achievement, and personal goals than did ads in South Korea. In line with this, another content analysis (Kim & Markus, 1999) showed that South Korean ads were more likely than U.S. ads to use conformity themes and less likely to use uniqueness themes. Website content in individualistic and collectivistic societies also appears to vary along similar lines (see Shavitt, Lee, & Torelli, 2009, for a review).

Cultural differences in the persuasiveness of these types of appeals follow a similar pattern. In a cross-national experiment (Han & Shavitt, 1994), appeals with individualistic themes (“Solo [detergent] cleans with a softness that you will love”) were more persuasive in the United States than in South Korea, and appeals with collectivistic themes (“Solo cleans with a softness that your family will love”) were more persuasive in South Korea than in the United States. A similar pattern was observed with individualistic and collectivistic appeals in an experiment in the United States and China

(Zhang & Gelb, 1996). Both sets of studies showed that the cultural differences were larger for products that were socially shared or visible to others, presumably because choices for such products are more subject to a culture's normative constraints.

Another study that examined the persuasiveness of appeals as a function of individual differences in self-construal (C. Wang & Mowen, 1997) found that U.S. participants' responses to individualistic versus collectivistic appeals for a credit card were predicted by whether they thought of themselves as independent and separate from others or interconnected with others. In short, both national culture and cultural self-construal predict the persuasiveness of individualistic and collectivistic appeals.

Evidence for cultural "matching" in the prevalence and persuasiveness of marketing appeals has been accompanied by research suggesting that culture moderates the psychological processes underlying persuasion. For instance, studies indicate that cultural factors influence not only how heavily social factors are weighted in attitude formation but also the processes by which they exert their impact (J. Aaker & Maheswaran, 1997). In research conducted in individualistic contexts, social factors such as endorsers or social consensus cues are more likely to be processed as peripheral cues, influencing persuasion only when elaboration likelihood is low (e.g., Maheswaran & Chaiken, 1991; Petty, Cacioppo, & Schumann, 1983). However, for people in collectivistic contexts, social factors are more likely to be processed as central information than as peripheral cues. Thus, they impact attitude formation under high-motivation conditions through elaborated processing. For instance, social consensus information (e.g., "80% of consumers surveyed prefer this brand") influences Hong Kong consumers' brand evaluations, regardless of their level of motivation (J. Aaker & Maheswaran, 1997), in contrast to American consumers, who consider social consensus cues primarily when they are not sufficiently motivated to engage in elaborated processing (Maheswaran & Chaiken, 1991). These findings suggest that for collectivistic compared to individualistic consumers, there may be less of a distinction between central arguments and peripheral cues, such as a brand's popularity or the attractiveness of its endorsers, and the influence of each type of information may follow different patterns.

Another implication of cultural differences for information processing addresses processes of incongruity resolution. Peng and Nisbett (1999) suggest that East Asians are more likely than Westerners to accept duality and contradiction. In line with this, they find that European Americans tend to differentiate between arguments, choosing which one is true, whereas the Chinese tend to seek a “middle way” to reconcile opposing arguments. Similar patterns have been observed in consumer research. When exposed to incongruent information in decision making (e.g., a relatively unlikable endorser presented together with positive attributes of a product), consumers in individualistic contexts focus on and rely primarily on the more diagnostic information (positive product attributes) (J. Aaker & Sengupta, 2000; Maheswaran & Chaiken, 1991). For example, when presented with negative endorser information and positive product attributes, American consumers were likely to elaborate on more diagnostic product evaluations, and neglect less diagnostic endorser information, in order to resolve the incongruity. In contrast, in collectivistic contexts, consumers may not perceive things to be incongruous just because they differ in valence. Instead, they exhibit an integrative approach when faced with evaluatively inconsistent data, combining various informational pieces together to evaluate products (J. Aaker & Sengupta, 2000). Thus, Chinese consumers in Hong Kong did not increase their elaboration on product attributes, presumably because they did not feel the need to resolve incongruity.

Culture and Consumer Peer-to-Peer Interactivity

Cultural differences may also be observed in the quantity and nature of interactions among agents in the marketplace. Consider this question: Why did eBay fail in the Chinese market? Soon after eBay entered the Chinese market in 2004, Taobao arose on the horizon as its competitor. According to iResearch, a Beijing-based research firm, consumers indicated higher satisfaction with Taobao (77%) than with eBay (62%). The difference in satisfaction can be attributed to a unique feature of Taobao’s that eBay overlooked: Taobao facilitated interactions between buyers and sellers via instant messaging, reflecting the desires of Chinese consumers for

interpersonal connections as a way to build trust (Lafevre, 2013). Despite eBay's formidable size and strengths, in the end, it only managed to gain a 29% market share and withdrew from the Chinese market in 2006.

As the eBay case illustrates, cultural differences exist in the nature of peer-to-peer interactivity desired by consumers. For example, systematic examination of the interactivity that is possible on U.S., U.K., Japanese, and South Korean corporate websites revealed that these interactions tend to be culturally patterned (Cho & Cheon, 2005). Western (vs. Eastern) marketers tend to develop websites that facilitate consumer–marketer interactivity (i.e., interactions between consumers and firms). For example, Western (vs. Eastern) websites have more functions that allow new product proposals and online discussion with sales representatives. On the other hand, although the Eastern websites also have such features, Eastern (vs. Western) marketers are more likely to develop websites that stress consumer–consumer interactivity (i.e., interactions between consumers). For example, Eastern (vs. Western) websites have more features that allow online communities and user groups to interact (Cho & Cheon, 2005).

These differences suggest that firms should also consider cultural differences in word of mouth (WOM), as this is another form of peer-to-peer interactivity. WOM refers to consumer–consumer communication about consumption (Carl, 2006; Godes et al., 2005; Moore, 2012). WOM has significant marketing implications, because it can drive new customer acquisitions (Schmitt, Skiera, & Van den Bulte, 2011) and sales (Chevalier & Mayzlin, 2006; Godes & Mayzlin, 2009). Thus, stimulating and managing WOM is a major priority for marketers. Cultural differences in WOM patterns align with cultural values such as conformity in collectivistic cultures (e.g., South Korea) and self-expression in individualistic cultures (e.g., the U.S.) (Kim & Markus, 1999; Kim & Sherman, 2007). For instance, conformity values can lead people in collectivistic (vs. individualistic) cultures to rely more on peer endorsements. In the context of a textbook shopping website, listing peer customer endorsements in the form of short quotes from students at the same university had a greater influence on students in Hong Kong than on students in Australia (Sia et al., 2009).

These cultural differences may be observed at both firm and individual consumer levels. For instance, in a study of industrial buyer behavior, the number of WOM referral sources (i.e., personal information sources the

buyer consults beyond the seller, such as colleagues or members of one's company's network) utilized by firms when they searched for service providers varied by cultural context (Money, Gilly, & Graham, 1998). Japanese firms operating in Japan and in the United States used 78% more referral sources than did U.S. firms when considering their operations in both countries. In the United States, Japanese (vs. U.S.) firms used 340% more referrals (Money et al., 1998). In other words, Japanese (vs. U.S.) firms utilized their personal networks and sources more, regardless of their situated locations. For instance, one manager of a Japanese company commented "Our attorney was referred to us by the municipal agency that regulates our business (public works construction company)" (Money et al., 1998, p. 84). Therefore, in order to do business with Japanese firms, U.S. managers should take this unique cultural characteristic into account and try to build relationships with the intermediaries of Japanese firms (e.g., banks).

Additional evidence suggests that consumers not only use WOM but also generate WOM in a manner that reflects their cultural contexts (Fong & Burton, 2008; Lai, He, Chou, & Zhou, 2013). User-generated content from 5,993 discussion postings to U.S.- and China-based discussion boards revealed that posts on the China-based (vs. U.S.-based) discussion boards were more likely to seek information and advice from others about their opinions, and were less likely to provide information to others (Fong & Burton, 2008). In line with this finding, online customer reviews in China (on *amazon.cn*) and the United States (on *amazon.com*) revealed that American versus Chinese reviews were more self-expressive in the sense that they provided their personal opinions on products and contained more recommendations to others (Lai et al., 2013).

Taken together, these findings suggest that cultural values, such as conformity in collectivistic cultures and self-expression in individualistic cultures, can shape how consumers or buyers utilize corporate websites, and how they respond to and engage in WOM with others when making purchase decisions. Overlooking these cultural characteristics may result in failure in global markets, as illustrated by the eBay case in China.

THE HORIZONTAL–VERTICAL CULTURAL DISTINCTION

Current conceptualizations of individualism and collectivism are broad and multidimensional (Oyserman, Coon, & Kimmelmeier, 2002; Shavitt, Lalwani, Zhang, & Torelli, 2006a; Shavitt, Zhang, Torelli, & Lalwani, 2006b; Triandis & Gelfand, 1998). Although the broad-based cultural distinction allows us to understand consumers with different cultural backgrounds, there is increasing attention paid to cultural classifications that address how hierarchy and power are patterned across societies, and their manifestations in attitudes and behaviors. Recent research has productively built on horizontal (valuing equality) and vertical (emphasizing hierarchy) distinctions within individualism and collectivism (Lalwani, Shavitt, & Johnson, 2006; Shavitt, Johnson, & Zhang, 2011; Triandis, 1995; Triandis & Gelfand, 1998). The vertical–horizontal distinction refers to the nature and importance of hierarchy in interpersonal relations (Singelis, Triandis, Bhawuk, & Gelfand, 1995; Triandis, 1995; Triandis, Chen, & Chan, 1998; Triandis & Gelfand, 1998). Individuals with a vertical orientation emphasize status enhancement, whereas individuals with a horizontal orientation exhibit a focus on interpersonal support and common goals. Applying the horizontal–vertical distinction to collectivism–individualism results in four distinct and independent cultural orientations: vertical individualism (VI), horizontal individualism (HI), horizontal collectivism (HC), and vertical collectivism (VC). Individuals, as well as societies, differ in the degree to which they emphasize each of these types of cultural values.

In VI societies (e.g., the United States, the United Kingdom, and France), people focus on improving their own status and distinguishing themselves from others via competition, achievement, and power. In HI societies (e.g., Sweden, Denmark, and Norway), people value uniqueness and distinctiveness from groups. In HC societies such as Brazil, people value sociability and interdependence with others within an egalitarian framework (Torelli & Shavitt, 2010). In VC societies (e.g., Korea, Japan), people prioritize goals of their ingroups over their personal goals (Triandis & Gelfand, 1998). In addition to differences between countries, there are differences in horizontal–vertical orientations within country by ethnic cultural groups. For instance, Hispanic Americans show a greater HC

tendency than do European Americans and a lesser VI tendency (Torelli et al., 2015; Torelli & Shavitt, 2010).

The importance of the horizontal–vertical distinction has been discussed and investigated in a number of consumer-behavior contexts (Meyers-Levy, 2006; Shavitt & Cho, 2016; Shavitt et al., 2006a). The horizontal–vertical distinction is predictive of consumers’ personal values, self-presentations, responses to brands and persuasive communications, and other consumer outcomes. In this section, we review relevant consumer research topics that have been investigated in relation to horizontal–vertical cultural differences.

Advertisements as Cultural Artifacts

As previously discussed, several studies have established that the content of advertising appeals tends to vary across cultures (Alden, Hoyer, & Lee, 1993; Choi & Miracle, 2004; Han & Shavitt, 1994; Kim & Markus, 1999). However, the majority of previous findings have focused on cultures that differ in individualism and collectivism (or independent vs. interdependent self-construal), such as the United States and South Korea.

Values associated with horizontal and vertical cultural orientations are also reflected in advertisements. Indeed, the articulation of the horizontal and vertical categories extends predictions beyond those based on the broad individualism–collectivism cultural classification. For instance, an analysis of over 1,200 magazine ads in five countries (Denmark, South Korea, Poland, Russia, and the United States) revealed that ads in vertical cultures (e.g., the United States and South Korea) put more emphasis on status, luxury, and prestige than do ads in horizontal cultures (e.g., Denmark) (Shavitt et al., 2011). For example, in vertical cultures, ads may use endorsers identified as Ivy League graduates and label brands as “award-winning.” On the other hand, uniqueness benefits were more prevalent in ads in an HI culture (Denmark) than in countries that fall into vertical cultural categories. For instance, such ads may highlight how a product can reflect “your personality.” These patterns would not have been predicted by analyses based solely on an individualism–collectivism classification.

Brands and Cultural Orientation

Apple's famous slogan, "Think Different," conveys values of openness and self-direction. However, the appeal of this slogan to consumers may vary depending on their cultural orientation (Torelli, Özsomer, Carvalho, Keh, & Maehle, 2012). Like the Apple slogan, brands themselves can be characterized as possessing human-like characteristics, such as values and traits (J. Aaker, Vohs, & Mogilner, 2010; Allen, Gupta, & Monnier, 2008). For instance, when Aaker, Vohs, and Mogilner (2010) subtly manipulated the Internet domain name of an organization (*a dot-org* vs. *dot-com*), they found that people perceive non-profit organizations (e.g., *www.mozilla.org*) to be more associated with warmth-related traits (e.g., warm, kind, generous) than for-profit organizations. On the other hand, people perceive for-profit organizations (e.g., *www.mozilla.com*) to be more associated with competence-related traits (e.g., competent, efficient, effective) than nonprofit organizations (J. Aaker et al., 2010).

Similarly, consumers tend to prefer brands that resonate with their value priorities as a function of their cultural orientations (Torelli et al., 2012). For example, having an HC cultural orientation is positively related to liking a brand that conveys self-transcendence values in its advertisement (e.g., "Supporting humanitarian programs in developing countries because we care about building a better world"), whereas having a VC cultural orientation is positively associated with liking a brand that conveys conservatism values in its advertisement (e.g., "The status quo in luxury watches. A tradition of classic designs and impeccable workmanship for 115 years"). Having a VI cultural orientation predicts liking a brand that conveys self-enhancement (e.g., "An exceptional piece of adornment that conveys your status and signifies your exquisite taste"), whereas an individual's HI cultural orientation predicts liking a brand that conveys openness (e.g., "A travel companion to help you live an exciting life full of adventures waiting around every corner") (Torelli et al., 2012). These findings suggest that even within collectivistic (or individualistic) cultures, people respond favorably to different values in brand advertising as a function of their own horizontal-vertical cultural orientations. If brands want to succeed in global markets, they should consider which brand values most resonate with their target consumers' horizontal or vertical cultural orientations.

Culturally Patterned Conceptualizations of Power

Conceptualizations of power can differ as a function of horizontal and vertical individualism and collectivism (Torelli & Shavitt, 2010). This cultural patterning of power concepts can be observed both at the individual and cultural group levels. People with a predominantly VI cultural orientation tend to view power in personalized terms; that is, power is seen as a tool to advance their own personal status and prestige. On the other hand, people with a predominantly HC cultural orientation conceptualize power in socialized terms; that is, power is seen as a tool to benefit and help others. This has a number of implications in consumer contexts, where products are routinely marketed as markers of power and status. For instance, a VI cultural orientation predicts the liking of brands that symbolize personalized power values of status and prestige, whereas an HC orientation predicts an affinity for brands that embody socialized power values that emphasize concern for the welfare of others (Torelli & Shavitt, 2010, Study 3). Moreover, these relations emerge across cultural groups. For example, Brazilians, who score relatively high on an HC orientation (compared to European Americans, Canadians, and East Asians), tend to prefer brands that symbolize prosocial values more than do the other cultural groups. Norwegians, who score relatively low in VI orientation, tend to prefer brands that symbolize personalized power values less than do all the other groups. A multilevel analysis further indicated that people's VI and HC cultural orientations partially mediated cultural group-level differences in liking for these respective types of brands (Torelli & Shavitt, 2010, Study 3). It should be noted that these four cultural orientations show strong divergent validity at the individual level of analysis (Triandis & Gelfand, 1998). In fact, some researchers have found no significant correlations between VI and HC or between VI and HI (Singelis et al., 1995). However, low to moderate positive correlations have been reported between HC and HI ($r = .20, p < .01$) and VC and VI ($r = .14, p < .05$) (Singelis, et al., 1995).

Injunctive norms applied to power holders also vary by cultural orientation, and the application of these norms predicts consumer judgments in a range of business and service settings (Torelli et al., 2015). European Americans (i.e., people high in VI) tend to conceptualize power in

personalized terms and endorse the misuse of power (e.g., “Sometimes it’s okay to take credit for one’s staff members’ ideas, because later they’ll do the same thing”) (Torelli & Shavitt, 2010). To mitigate possible misuse of power, therefore, cultures that adopt a personalized view of power tend to cultivate injunctive norms of exercising power with justice and equity (Torelli et al., 2015). In contrast, because Hispanics (i.e., people high in HC) tend to conceptualize power in socialized terms, injunctive norms for exercising power incorporate socioemotional concerns with others’ well-being. Thus, Hispanics often apply injunctive norms of compassion when judging power holders.

For instance, European Americans evaluate a negotiator more favorably when the negotiator exercises power in accordance with cultural norms of justice (e.g., pay contractors evenly), whereas Hispanics evaluate the negotiator more favorably when the negotiator exercises power in accordance with cultural norms of compassion (e.g., pay a contractor who is dealing with a stressful familial issue more than the one without such an issue). These differences also have implications for consumer satisfaction with powerful service providers in a service interaction (e.g., physicians in a clinic) (Torelli et al., 2015). Indeed, when power was made salient, European American patients’ satisfaction with a health care provider became more dependent on perceptions of justice (e.g., appropriate allocation of resources and respect), whereas Hispanic patients’ satisfaction with a health care provider became more based on perceptions of compassion (e.g., emotional reassurance, sympathy, and caring).

Consistent with this logic, beliefs about others’ status are also culturally contingent (Torelli, Leslie, Stoner, & Puente, 2014). Individualism is positively correlated with a tendency to associate high-status individuals with attributes linked to competence (e.g., ambitious, creative, and intelligent), whereas collectivism is positively correlated with a tendency to associate high-status individuals with attributes linked to warmth (e.g., caring, friendly, and generous). Reflecting these culturally shaped status beliefs, individuals from the United States as compared to those from Latin America were more likely to engage in competence-signaling behaviors (e.g., working late to be sure one did the best job possible on a work assignment) in order to acquire workplace status. In contrast, Latin Americans as compared to U.S. Americans are more likely to engage in warmth-signaling

behaviors (e.g., volunteering outside one's working hours to help coworkers with personal issues) in order to gain workplace status (Torelli et al., 2014). In line with this, Latinos prefer workgroups that emphasize both task and interpersonal harmony, whereas Anglo Americans prefer workgroups that are task-oriented (Sanchez-Burks, Nisbett, & Ybarra, 2000).

Culturally Shaped Information Processing

Horizontal and vertical cultural orientations are also associated with distinct mindsets and cognitive processes. Cultural mindsets refer to a set of mental representations or cognitive schemas that are culturally congruent (e.g., knowledge about the self and the world; Oyserman, 2011; Oyserman, Sorensen, Reber, & Chen, 2009). For instance, culturally distinct mindsets are triggered when power concepts are cued, even when processing information about nonsocial targets such as brands (Torelli & Shavitt, 2011). Individuals high (vs. low) in VI tended to stereotype information when primed with personalized power and were better at recognizing information that was congruent with the McDonald's stereotype of unhealthiness and convenience ("convenient, greasy, unhealthy, flavorful, and fast"). There was no such difference in stereotyping between individuals high and low in VI when they were primed with socialized power or when they were not primed with either type of power. On the other hand, individuals high (vs. low) in HC who were primed with socialized power tended to individuate in their information processing, showing better recall and recognition for information incongruent with the McDonald's stereotype ("healthy, cozy, and delicate"). There was no such difference in individuating between those high and low in HC when they were primed with individualized power or when there was no priming. These culturally distinct patterns in information processing presumably occur because they address distinct power goals. People with a VI cultural orientation—who view power in personalized terms—may adopt a stereotyping mindset to help defend their powerful status over others (Fiske, 1993). On the other hand, those with an HC cultural orientation—who view power in socialized terms—may adopt an individuating perspective to accurately form impressions of others in

order to meet their needs (Goodwin, Gubin, Fiske, & Yzerbyt, 2000; Russell & Fiske, 2010).

Although not specific to the horizontal–vertical cultural distinction, it is worth noting that national identity may also cue cultural mindsets and shape consumers’ reactions to the presence of nutritional information (Gomez & Torelli, 2015). For instance, food enjoyment is central to the French culture. Thus, when French identity is made salient, a food-enjoyment cultural mindset is activated among French consumers, which subsequently leads French consumers to evaluate food less favorably when nutritional information is present (vs. absent). Furthermore, French consumers reported greater difficulty in processing nutritional information (as indicated by rating the ease of processing the nutrition information on a 7-point scale) when their French identity was made salient (vs. not made salient). This is because nutritional information is utilitarian in nature and opposed to a food-enjoyment cultural mindset. These outcomes were not observed among American consumers, for whom food enjoyment is not central to their cultural identity. Therefore, when promoting their foods to consumers, marketers should be careful in delivering nutritional information, because emphasizing such utilitarian aspects of foods may backfire with consumers who hold a food-enjoyment cultural mindset.

A Similar Construct to Horizontal–Vertical Distinctions: Power Distance Belief

Related to the horizontal–vertical distinction, power distance also addresses power and hierarchy beliefs, and offers additional insights for understanding consumer behavior. As a culture-level variable, “power distance” refers to the degree to which power hierarchies in organizations are expected and accepted (Hofstede, 1984, 2001; Oyserman, 2006). As an individual-level variable, “power distance belief” (PDB) captures the degree to which individuals in a culture accept power disparity (Winterich & Zhang, 2014). PDB scores can predict how individuals think and behave in the marketplace (Yoo, Donthu, & Lenartowicz, 2011). Although power distance and the horizontal–vertical distinction address related notions, there are conceptual and structural differences between them (Shavitt et al., 2006a;

2006b). Conceptually, power distance captures the degree to which the less powerful individuals in a society accept inequalities in power, whereas the horizontal–vertical distinction refers to differences in the emphasis on hierarchy in society. Structurally, both power distance and PDB vary along a single dimension (high to low), whereas the horizontal–vertical distinction reflects distinct categories nested within individualism and collectivism. Therefore, one should be careful in inferring power distance from a horizontal–vertical distinction.

Research on power distance has partly been stimulated by an interest in prosocial consumer behaviors, such as making donations (Duclos & Barasch, 2014; Winterich & Zhang, 2014). Those high in PDB (vs. low in PDB) accept inequality rather than feel a responsibility to change it (Bourdieu, 1984; Miller, McIntyre, & Mantrala, 1993). Therefore, PDB is negatively associated with perceived responsibility to aid others and, thus, with charitable behavior (Winterich & Zhang, 2014). However, the type of needs that the charitable behavior is intended to address—uncontrollable (e.g., disaster) versus controllable (e.g., overweight)—can moderate the relationship between PDB and charitable behavior: When the need is uncontrollable, even individuals with high PDB feel a responsibility to provide help to others. In addition, when communal norms (vs. exchange norms) are salient, PDB does not predict lower engagement in charitable behavior, as communal norms increase everyone’s felt responsibility for others’ welfare (Winterich & Zhang, 2014).

PDB can shape one’s consumption patterns in the marketplace as well. For example, PDB can predict how consumers judge the price–quality relation (Gao, Winterich, & Zhang, 2016). Consumers in general have a tendency to infer the quality of a product from its price, which is termed a “price–quality judgment” (Cronley, Posavac, Meyer, Kardes, & Kellaris, 2005; Kardes, Cronley, Kellaris, & Posavac, 2004), but consumers who are high (vs. low) in PDB have a greater tendency to infer a product’s quality from its price, because they have a stronger need for structure (Lalwani & Forcum, 2016). People with a higher need for structure are more likely to use heuristics and engage in stereotyping, and price can be an easy way to categorize products.

PDB can be also predictive of impulsive buying (Zhang, Winterich, & Mittal, 2010). Individuals who are high (vs. low) in PDB are less likely to

engage in impulsive buying. However, this effect holds only for vice products (e.g., a Snickers bar, potato chips) and not for virtue products (e.g., a granola bar, an apple). In other words, those low (vs. high) in PDB buy more vice products and show no difference in buying virtue products. This can be interpreted as a manifestation of self-control, such that higher PDB activates control-related processes.

In summary, cultural variables that address power and hierarchy beliefs and horizontal–vertical cultural orientations refine the broader individualism–collectivism distinction and afford novel predictions about consumer behavior. As discussed, a consideration of horizontal–vertical cultural orientations can clarify how individuals conceptualize power and status, help to predict which advertising appeals will be most effective, and suggest the values that brands should embody. We have also covered the implications of PDB, which addresses the acceptance of power disparities, in various consumer domains such as prosocial behavior, impulsive buying, and price–quality judgments. In the next section, we discuss the implications of holistic–analytic thinking styles in the consumer domain.

HOLISTIC–ANALYTIC THINKING STYLES IN CONSUMER CONTEXTS

As reviewed previously, cultural orientations can vary in their levels of individualism–collectivism, horizontal–vertical orientations, and PDB. In addition to orientation-based drivers of cultural differences, an emerging stream of research investigates how differences in thinking style affect consumer outcomes. This section reviews the distinction between holistic and analytic thinking styles (Masuda, Russell, Li, & Lee, [Chapter 8](#), this volume; Nisbett, Peng, Choi, & Norenzayan, 2001), connects thinking style to previously reviewed cultural distinctions, and outlines relevant findings and implications within the consumer domain.

Holistic thinking and analytic thinking primarily differ in how one perceives an object’s relationship with its context. Holistic thinkers tend to adopt a big-picture view that emphasizes the interconnectedness between individual objects in the context. As a result, holistic thinkers often explain and predict events based on contextual factors. In contrast, analytic thinkers

tend to separate individual objects from their context and focus on the objects' distinct attributes to assign them to categories. Hence, analytic thinkers often use information about the object's category to explain and predict events (Nisbett et al., 2001).

In addition, holistic and analytic thinking styles tend to correlate with established Eastern and Western cultural distinctions. People from Eastern cultures tend to be predominantly collectivistic and construe themselves as interdependent with others (Markus & Kitayama, 1991; Triandis, 1995). Easterners also tend to adopt a holistic thinking style, which influences their tendency to see connections between individual objects and the environment. By contrast, people from Western cultures tend to be primarily individualistic and construe themselves as independent of others. Westerners primarily adopt an analytic thinking style, in which they separate and distinguish objects from their contexts (Masuda & Nisbett, 2001; Nisbett et al., 2001; Oyserman & Lee, 2007). These culturally distinct thinking styles are also consistent with decision rules that Westerners frequently use (e.g., one attribute is more important or diagnostic than the other) versus the compromise rule that Easterners frequently use (e.g., both attributes are important; Briley, Morris, & Simonson, 2000), in line with the research on incongruity resolution discussed earlier (J. Aaker & Sengupta, 2000). In the sections that follow, we discuss how differences in thinking style can influence consumer attitudes and behaviors toward brands, prices, and retail settings.

Brands

Brands are more than the logo or tagline that we view in promotions. Brands tell a story that businesses intentionally craft to engage and resonate with their audience. Some brand stories are so ingrained in our consumer memory that the brands themselves become culturally symbolic icons (Torelli & Ahluwalia, 2012). Next, we discuss the ways that cultural differences in thinking style can affect how individuals recall information in brand stories and use information to respond to a brand's new offerings.

Thinking Style Predicts How Consumers Use Brand Information

The information included in a brand's story is not always positive. Several brand stories are riddled with scandal, product recalls, and other negative information. One might assume that all consumers react similarly to negative brand information; for example, beliefs about a brand's safety may change after learning about a recent product recall. However, cross-cultural research has demonstrated how differences in thinking style affect the way negative information impacts consumers' product beliefs.

Who do consumers perceive to be responsible when they encounter negative information about a brand? Earlier, we mentioned that analytic thinkers are more likely than holistic thinkers to use information about the object's category to explain and predict events. This tendency also affects how people with different thinking styles attribute the causes of events. For instance, analytic thinkers are more likely to attribute causality to the actor's internal dispositions rather than to external causes (Nisbett et al., 2001). As a result, consumers with analytic (vs. holistic) thinking styles may also report greater changes in their beliefs about a product when they are exposed to negative brand information. In one study, Monga and John (2008) primed thinking style and asked participants to read a negative press release about Mercedes-Benz. Participants primed to think analytically were more likely to attribute the cause of the negative information to the brand internally, whereas participants primed to think holistically considered a broader set of reasons when explaining the negative brand information.

Thinking Style Predicts How Consumers Evaluate Brand Extensions

Marketers often leverage successful brand names to extend their reach into new product categories. For example, Huggies might extend its diaper brand into the baby stroller category. Research on brand extensions indicates that consumers will positively evaluate brand extensions if they have a positive attitude toward the parent brand and perceive an adequate fit between the parent and extension category (D. Aaker & Keller, 1990). Cross-cultural

research has shown that thinking style affects how people categorize objects (Jain, Desai, & Mao, 2007; Ji, Zhang, & Nisbett, 2004; Nisbett et al., 2001). Therefore, thinking styles should also predict consumers' brand extension evaluation based on their categorization of the parent and extension products.

Monga and John (2007) pretested various fictitious brand extensions that consumers perceived to have low fit with Kodak (e.g., filing cabinets) and asked separate groups of Indians (holistic thinkers) and Americans (analytic thinkers) to evaluate them. They found that Indians (vs. Americans) perceived greater fit between Kodak and the extensions, and evaluated the brand extensions more favorably. Moreover, when holistic thinking was primed, participants became more favorable toward the brand extensions. Related research suggests that consumers with an interdependent self-construal (i.e., predominantly holistic thinkers) are better able to think of alternative ways to relate an extension to the parent brand and to find relationships between them, perceiving a greater fit, and therefore evaluate brand extensions more favorably than analytic thinkers do (Ahluwalia, 2008).

However, the difference between analytic and holistic thinkers in brand extension evaluation tends to disappear when consumers evaluate prestige (vs. functional) brand extensions (Monga & John, 2010). Compared to functional brands (e.g., Maytag), prestige brands (e.g., Vera Wang) tend to have more abstract and symbolic brand concepts. Abstract and symbolic brand concepts facilitate finding a basis of fit for extensions in distant product categories (e.g., Vera Wang bedding) (Park, Milberg, & Lawson, 1991). As previously referenced, holistic thinkers generally think more contextually and see more relationships when evaluating the fit between brand extensions and parent brands (Monga & John, 2007). However, analytic thinkers are also able to see relationships or associations between prestigious parent brands and their extensions (Monga & John, 2010). These findings suggest that marketers should consider consumers' prestige perceptions when extending their global brands into distant product categories.

Prices

Price, one of the four P's in marketing (*price, product, place, and promotion*), is an important topic of study, because a firm's pricing decisions affect profit margins, supply, demand, and marketing strategy. Consumers typically perceive prices to be either a representation of the good's internal composition (e.g., features, materials) or a representation of its external environment (e.g., competitors' prices). Accordingly, research has defined the reference points from which consumers perceive prices as internal reference prices (IRP) and external reference prices (ERP) (Helson, 1964; Kalyanaram & Winer, 1995). As previously discussed, analytic thinkers tend to view objects as independent of their contexts and attribute causality for events to the object's internal disposition, whereas holistic thinkers view objects as interdependent with their context and are more likely to attribute causality to external sources (Nisbett et al., 2001). Consistent with these accounts, C. Chen (2009) found that consumers primed with an independent self-construal were more favorable toward prices influenced by internal factors (IRP) instead of external factors (ERP). In contrast, consumers primed with an interdependent self-construal were more influenced by ERP than by IRP. These results were explained by differences in participants' tendencies to perceive connectedness and separateness, key elements of holistic and analytic thinking styles.

Thinking Style Moderates Price–Quality Judgments

A foundational axiom in the marketing literature is that consumers tend to judge quality based on price (Rao & Monroe, 1988, 1989). As noted earlier, a broad body of research supports this notion and shows that as the price of a product increases, so do quality perceptions (Dawar & Parker, 1994; Kardes et al., 2004), an effect that has been dubbed a “marketing universal” (Dawar & Parker, 1994). However, cross-cultural research on this robust phenomenon has demonstrated that thinking styles moderate the strength of the price–quality relation (Lalwani & Shavitt, 2013). Specifically, consumers who adopt a holistic versus analytic thinking style are more likely to use price to judge quality because of their tendency to perceive interrelations between price and other product elements.

Thinking Style Moderates Perceptions of Price Patterns

Thinking styles also predict how consumers view patterns in price changes. Because holistic thinkers tend to focus on the interrelations between objects, they are unlikely to assume that any particular object will remain stable over time (Nisbett, 2003). Instead, holistic thinkers expect trends to fluctuate. In contrast, analytic thinkers view objects as independent of other objects and are therefore more likely to assume that objects remain stable over time. Taken together, this suggests that analytic thinkers expect a linear change such that any future change should closely follow previous trends. Consistent with this logic, analytic thinkers (e.g., Canadians) are more likely than holistic thinkers (e.g., Chinese) to make judgments based on recent trends when predicting future stock market trends and making investment decisions. Furthermore, analytic (vs. holistic) thinkers are less willing to buy stocks when prices follow a decreasing trend, and are more likely to buy stocks when they follow an increasing trend (Ji, Zhang, & Guo, 2008).

Retail Settings

People with analytic versus holistic thinking styles may also differ in their responses to retail settings. Below, we discuss research that has demonstrated robust effects of thinking style on perceptions of products and product displays.

In retail settings, marketers arrange products within a variety of contexts. For example, a clothing store manager may need to decide the kind of background to use when putting a new pair of jeans on display. Should the background resemble or contrast with the jeans? Remember that analytic thinkers tend to “separate and distinguish” objects from their context, whereas holistic thinkers “integrate and connect” objects with their context (Oyserman & Lee, 2007). Thus, connecting the target object with the context might influence how holistic (vs. analytic) thinkers view the target itself.

This matters in retail settings, because differences in consumer thinking style can affect the way product perceptions change when the background changes, even when the product does not. Specifically, research has

demonstrated that analytic thinkers are more likely to view a product and its context as separate elements, whereas holistic thinkers view the product and the context as continuous parts of a larger whole. In one study, Zhu and Meyers-Levy (2009) primed participants' self-construal and asked them to evaluate a mug on either a glass or wooden table. Participants primed with an interdependent self-construal assimilated the object and its context, evaluating the mug as more trendy when placed on the glass table, but more natural when placed on the wooden table. However, participants primed with an independent self-construal contrasted the object and its context, evaluating the mug as more trendy when placed on a wooden table, but more natural when placed on a glass table.

So far, we have discussed how consumers may use information inside a retail setting to make judgments. However, before a customer walks into a store, he or she might use information about the retailer (e.g., store reputation) to make judgments about the products inside. For example, self-construal predicts differences in how consumers make quality inferences based on a retail store's reputation (K. Lee & Shavitt, 2006). Specifically, participants primed with an interdependent (vs. independent) self-construal used a store's reputation to evaluate a microwave's quality. Interdependent participants evaluating a GE microwave sold at a high-end department store viewed it more favorably than the same microwave sold at Kmart (K. Lee & Shavitt, 2006). These findings are consistent with the logic that holistic thinkers assimilate an object and its context when making judgments (e.g., Zhu & Meyers-Levy, 2009).

In summary, research into culturally patterned differences in thinking styles has addressed a broad range of consumer attitudes and behavior. As we have discussed, analytic and holistic thinkers can differ in the ways that they interpret and use brand, price, and retail information. In the next section, we review how the fit between culture and self-regulatory goals can affect consumer behavior.

SELF-REGULATION AND REGULATORY FOCUS

There are broad cultural differences in the overall tendency to self-regulate versus engage in impulsive consumption. For example, a survey of

consumers in Australia, the United States, Hong Kong, Singapore, and Malaysia revealed that consumers with a chronic independent (vs. interdependent) self-construal were more likely to participate in impulsive purchasing behavior (Kacen & Lee, 2002). Also, chronic individualism or independence predicted greater likelihood to engage in beer consumption (Zhang & Shrum, 2009). Alcohol consumption was used as a proxy of impulsive consumption, because it has been related to traits associated with impulsivity (e.g., lack of willpower; Hoch & Loewenstein, 1991). At both the country (42 countries) and the state level (in the United States) of analysis, individualism was positively correlated with beer consumption.

A close fit between one's self-construal and one's cultural context can also benefit self-regulation, specifically, in maintaining a healthy diet (Levine et al., 2016). In the United States, being independent predicts healthy eating, and the relationship is mediated by autonomy. On the other hand, in Japan, being interdependent predicts healthy eating, and the relationship is mediated by positive relations with others. This is presumably because eating healthy is culturally normative in both cultural contexts, and adhering to normative cultural values facilitates making healthy choices.

Self-regulation toward a goal can be focused on either promotion or prevention objectives. Acting as self-regulatory guides, these two objectives help direct consumers' attention, attitudes, and behaviors (Higgins, 1997). Promotion-focused self-regulation is concerned with potential gains and aspirations, whereas prevention-focused self-regulation is concerned with potential losses and the fulfillment of responsibilities. People with a promotion focus pursue growth and achievement goals with eagerness and are sensitive to potential gains. In contrast, people with a prevention focus pursue safety and duty goals with vigilance and are sensitive to the presence or absence of negative outcomes and to potential losses. Promotion focus resonates with the goals of the independent self (e.g., autonomy, achievement), whereas prevention focus resonates with the goals of the interdependent self (e.g., fulfilling obligations, fitting in with others) (Heine, Lehman, Markus, & Kitayama, 1999).

In this section, we discuss the benefits of fit between culture and self-regulatory goals that span relevant consumer domains of persuasion, willingness to pay price premiums, and impulsive consumption.

Benefits of Regulatory Fit

Persuasion

Consumer outcomes are generally more favorable for marketers when marketing communications coincide with consumers' self-regulatory goals (J. Aaker & Lee, 2001; Hong & Lee, 2008; Keller, 2006). This robust matching effect has been shown in a number of ways. For instance, people with a dominant independent (interdependent) self-construal tend to perceive promotion-focused information as more (less) important than prevention-focused information (e.g., they rate scenarios as being more important and critical on 7-point scales) (A. Lee, Aaker, & Gardner, 2000). Thus, people with an independent self-construal perceived a message to be more important when it emphasized potential gains (e.g., "If you pick Alternative B, there is a two-thirds probability that you will not win any of the \$1,200 worth of prizes and a one-third probability that you will win all \$1,200 worth of prizes") than when the message emphasized potential losses (e.g., "If you pick Alternative B, there is a two-thirds probability that you will lose all of the \$1,200 worth of prizes and a one-third probability that you will not lose any of the \$1,200 worth of prizes"). In contrast, individuals with interdependent self-construal perceived a loss-framed (vs. gain-framed) message as more important. Moreover, consumers with distinct independent or interdependent self-views are more persuaded by strong arguments that align with their self-regulatory concerns, as opposed to arguments that do not (J. Aaker & Lee, 2001; Agrawal & Maheswaran, 2005; J. Wang & Lee, 2006).

Willingness to Pay

Consumers tend to be willing to pay a price premium for services that align with their dominant self-view and regulatory goals (H. Chen, Ng, & Rao, 2005). For instance, consumers with an independent self-view were more likely to pay for expedited delivery when the message was framed with a promotion focus (e.g., enjoy the product early). In contrast, people with an interdependent self-view were more willing to pay for the same service when the message was framed with a prevention focus (e.g., avoid delay in

receiving the product; H. Chen et al., 2005). These types of matching effects hold regardless of whether self-construal is measured (chronic) or manipulated (J. Aaker & Lee, 2001; Agrawal & Maheswaran, 2005; H. Chen et al., 2005).

Consumer Goals

Consumers vary in terms of whether they want to attain a goal target or maintain their current state, and culture appears to play an important role. For instance, Yang, Stamatogiannakis, and Chattopadhyay (2015) showed that independent and interdependent self-construal predict broad and robust differences in consumer goals. Independent consumers or contexts tend to have or to activate attainment goals such as achieving particular financial savings or weight loss objectives. In contrast, interdependent consumers or contexts tend to have or to activate maintenance goals such as keeping a consistent body weight or bank balance.

Moderators of Regulatory Fit Benefits

Brand Commitment

Brand commitment (e.g., consumers' public attachment or pledging to a brand) might determine when chronic (vs. situational) self-construal produces persuasion matching effects (Agrawal & Maheswaran, 2005). Advertising appeals consistent with an individual's chronic self-view are more persuasive when brand commitment is high, but appeals that are consistent with an individual's situational self-construal are more persuasive when brand commitment is low. This is attributable to the relationship between brand commitment and memory; that is, consumers with high brand commitment are likely to have a readily accessible knowledge base associated with the brand, which is linked to other chronically accessible knowledge in memory, such as one's self-view. Therefore, consumers' attention and attitudes are likely to follow their chronic (vs. situational) self-construal. Consumers with low brand commitment are less likely to link brand information with chronically accessible self-knowledge (Agrawal &

Maheswaran, 2005). Thus, their attitudes tend to follow their situational (vs. chronic) self-construal.

Consumer Involvement

Consumer involvement may also moderate self-regulatory matching effects. Consumers with a cultural inclination toward a particular self-regulatory focus (promotion or prevention) reported more favorable attitudes toward products that addressed their regulatory concerns only when they did not have the opportunity to deliberate or expend cognitive resources on the task (Briley & Aaker, 2006). For example, Chinese (vs. American) consumers showed more favorable attitudes toward prevention-focused (vs. promotion-focused) messages. However, when individuals were provided with a chance to deliberate on their thoughts, these cultural differences dissipated. The expected regulatory matching effects occurred only when participants could not deliberate during information processing, such as when they had limited cognitive resources because they had to memorize other information (e.g., 8-digit numbers) or were only given a short amount of time to process the information.

In conclusion, previous findings on culture and self-regulation suggest that individuals in collectivistic cultures tend to be more prevention-focused, whereas individuals in individualistic cultures tend to be more promotion-focused. Cultural differences in self-regulatory focus have considerable marketing implications, because fit between culture and self-regulatory goals can increase perceived persuasiveness of ad appeals, as well as consumers' willingness to pay price premiums. However, the strength and nature of these cultural differences are moderated by factors such as degree of deliberation in information processing and by brand engagement.

SELF-CONSTRUAL AND OBJECT RELATIONSHIPS

Consumers form relationships with possessions and brands to construct and communicate their self-concepts (Belk, 1988; Fournier, 1998; Kleine, Kleine, & Allen, 1995; Sirgy, 1982; Wallendorf & Arnould, 1988). One potential

manifestation of a strong self–object relationship is referred to as the “endowment effect,” or the tendency for owners to value their possessions more than potential buyers do (Kahneman, Knetsch, & Thaler, 1990; Thaler, 1980). The endowment effect has been demonstrated across numerous studies but has only begun to be examined cross-culturally (Maddux et al., 2010). Among several suggested explanations for the phenomenon (e.g., loss aversion, differences in salient emotions), one explanation posits that the endowment effect is driven by a self-referent cognitive bias due to mere ownership of an object (Beggan, 1992; Gawronski & Bodenhausen, 2007; Maddux et al., 2010). In other words, people value items they own more, because these items reflect some aspect of the self. Therefore, one might deduce that in a cultural context in which there is less emphasis on the self, the endowment effect might be diminished. Using this line of reasoning, Maddux et al. showed that the endowment effect is stronger (e.g., people assign more value to owned possessions) among people with an independent versus interdependent self-construal.

When possessions are also branded, the relationship between the object and the self often results in a perceived overlap between brands and consumers’ self-concept, which is referred to as a “self–brand connection” (Escalas, 2004). A consumer’s cultural self-construal can determine the pattern of brand relationships he or she forms. For example, it is relatively easy to understand why a consumer would see a high overlap between his or her self-concept and a brand (a self–brand connection) when the brand’s users are consistent with one of the consumer’s perceived ingroups, but see low overlap when the users represent an outgroup. However, research has shown that cultural self-construal determines whether consumers form low self–brand connections with brands associated with outgroups. Consumers with a chronic interdependent (vs. independent) self-construal are likely to report a higher self–brand connection with a brand used by outgroup members (Escalas & Bettman, 2005). Although this may seem counterintuitive, this result is in line with prior work that suggests people with an independent (vs. interdependent) self-construal have more prominent needs to differentiate themselves from outgroups (Kampmeier & Simon, 2001).

Whereas much of the consumer literature examines brand relationships based on a self-concept connection with the brand (e.g., Escalas & Bettman,

2005; Fournier, 1998), additional work posits that consumers can form group-level connections with brands, such as country-of-origin connections (e.g., Gürhan-Canli & Maheswaran, 2000). Swaminathan, Page, and Gürhan-Canli (2007) synthesized the literature on these two types of consumer-brand connections by demonstrating how cultural self-construal determines when each type of connection influences attitude change in response to negative brand information (e.g., a product recall). The authors found that consumers with high self-concept connections were more likely to counterargue negative brand information when an independent (vs. interdependent) self-construal was salient. In contrast, consumers with high brand country-of-origin connections were more likely to counterargue negative information when an interdependent (vs. independent) self-construal was salient.

Taken together, research has examined the ways that consumers' cultural self-construal can predict how they form relationships with possessions and brands. As noted earlier, the need to differentiate from outgroups is more prevalent among independents (vs. interdependents; Kampmeier & Simon, 2001). When consumers view themselves as independent of others, they tend to form self-concept connections with brands, are more likely than interdependents to resist forming relationships with brands used by outgroup members, and value owned objects more because they reflect the self. On the other hand, consumers who view themselves as interdependent with others tend to form group-level connections with brands, have weaker needs to differentiate from outgroup members, and are less susceptible to the endowment effect than those with an independent self-construal.

FUTURE DIRECTIONS

As we have reviewed, cross-cultural consumer research has built productively upon psychological theorizing. In so doing, it has addressed differences in consumer goals, information-processing patterns, self-regulatory processes, and consumer decisions as functions of a variety of cultural factors.

Cross-cultural perspectives have much to offer in aiding understanding of marketplace behavior. This is especially the case because much of the

extant knowledge about consumer phenomena has emerged from a traditional approach to attitudes and social cognition (Riemer et al., 2014). The development and expression of personal preferences, and choices rooted in these preferences, are foundational in Western contexts. Most perspectives assume, therefore, that personal preferences are key to achieving and predicting desired marketing outcomes (e.g., brand choice, brand loyalty). This approach, as developed in the West, may offer an incomplete account of the nature of consumer behavior in non-Western contexts. It is yet to address how consumers function in contexts in which maintaining relationships, fulfilling social roles, and being normatively appropriate are often more important than the independent formation and expression of personal preferences in the marketplace.

This means, for example, that in India compared to North America, personal preferences are less predictive of product choices (Savani, Markus, & Conner, 2008). Similarly, Indian employees are more likely than Americans to make choices consistent with what is expected by authority, irrespective of their personal preferences (Savani, Morris, & Naidu, 2012). In Japan and China, personal preferences for a “greener” world do not predict green behavior, yet such preferences are a strong predictor in the United States (Chan & Lau, 2001; Eom, Kim, Sherman, & Ishii, 2016). Furthermore, for Asian American children, choosing according to the preferences of close others is more satisfying and more likely to motivate behavior than choosing according to their own personal preferences, whereas the reverse is true for European American children (Iyengar & Lepper, 1999; Kitayama, Snibbe, Markus, & Suzuki, 2004; Uchida & Kitayama, 2009). As such, patterns of postchoice justification to reduce cognitive dissonance also vary by culture (Hoshino-Browne et al., 2005; Kitayama et al., 2004). For example, participants from a collectivistic background (Asian Canadians) were more likely to justify choices they made for their friends (vs. choices for themselves), whereas participants from an individualistic background (European Canadians) were more likely to justify choices they made for themselves (vs. choices for their friends; Hoshino-Browne et al., 2005).

Future work should focus on integrating such insights from the burgeoning field of cross-cultural research into theorizing about consumer behavior. In many non-Western contexts, an emphasis on obligations, others’ expectations, and norms is foundational. An approach that addresses

such influences (e.g., Riemer et al., 2014) can expand our focus to encompass how norms and situational guides influence consumer judgments and decisions across cultures.

CHAPTER 26

Culture and Creativity/Innovation

Chi-yue Chiu and Ying-yi Hong

In this chapter, we address three conceptual and empirical issues related to the reciprocal relationship of culture and creativity/innovation: (1) why societies with different cultures differ in creative and innovation performance; (2) how multicultural exposure and experiences enhance creativity; and (3) the roles of creativity and innovation in cultural change. The existing evidence shows that the level of creativity/innovation performance in a society is related to its mainstream cultural values (e.g., individualism, long-term orientation), availability of institutional support for innovation, and the prevailing norms of creativity in the society. Multicultural experiences foster individual creativity, whereas ethnic fragmentation in the society and the presence of a cultural fault line in teams lower creativity in the society and teams, respectively. Finally, cultural interactions facilitate cross-fertilization of ideas and promote cultural changes, but the motivation to preserve cultural purity may limit idea borrowing from other cultures and slow down innovation and cultural changes. We highlight in this chapter the marked differences in the relationships between culture and creativity/innovation at different levels of analysis (the individual, the group, and society levels).

Recent advances in research on culture, creativity, and innovation have provided some answers to three questions. First, do societies with different cultures differ in creative and innovation performance? If so, how? Second, do multicultural exposure and experiences enhance creativity? Third, what roles do creativity and innovation play in cultural change?

In this chapter, we review the latest research that addresses these three questions. Our review highlights the advantages of taking a multilevel approach in cultural-psychological research, because of the marked differences in the relationships between cultural and behavioral variables at different levels of analysis (the individual, the group, and society levels). For example, although individualist societies have higher innovation performance than do collectivist ones, comparisons of performance of individualists and collectivists have yielded mixed support for the creative benefits of individualism (Li, Kwan, Liou, & Chiu, 2013). In addition, although under most circumstances, individuals with richer multicultural experiences are more creative (Leung & Chiu, 2010), societies with higher levels of ethnolinguistic diversity have poorer innovation performance (Kwan & Chiu, 2018; cf. Zhan, Bendapudi, & Hong, 2015).

To resolve the seemingly inconsistent findings on the culture-creativity/innovation nexus, it is important to realize that there are different types of creativity and innovation outcomes. For example, creativity researchers have differentiated between small-c (creativity in everyday-life problem solving) and Big-C (highly novel and domain-appropriate works that have caused a refashioning of the domain; Gardner, 1993), whereas innovation researchers have distinguished between incremental and transformational innovation (Pavitt, 1991). Cultural and psychological factors that affect small-c and incremental innovation are different from those that influence Big-C and transformational innovation.

In addition, culture may affect creative performance through different routes. For example, culture may direct an individual's regulatory focus to gains versus losses, which in turn impacts the creative performance of the individual (Friedman & Forster, 2001, 2002). Culture may also shape the descriptive norms of creativity in the society, which in turn influence group processes and creative outcomes in work teams (Erez & Nouri, 2010; Morris & Leung, 2010).

Creativity and innovation involve different processes, including idea generation, idea selection and development, and idea implementation and marketing (Chiu & Kwan, 2010). Performance at different creativity and innovation processes is influenced by different psychological factors. For example, a focus on gains facilitates idea generation, whereas a focus on losses enhances persistence in idea implementation (Lam & Chiu, 2002).

Finally, as Donald (1991) put it, creativity involves the capacity for one thought to trigger another, leading to the chaining and progressive modification of thoughts and actions; this process enables evolution of culture. To understand how creative ideas evolve in a culture, we need to understand how creative ideas are communicated and how they inspire other ideas. In the psychological literature, “creativity” has been defined as mental processes that lead to novel and useful outcomes (Amabile, 1996). From a cultural-psychological perspective, we need to expand this definition, because creativity also involves the processes of inspiration and communication. To understand how culture influences creativity, it is not sufficient to just study how culture impacts individual creativity. What we need in addition are historical–spatial analyses that confer understanding of how ideas travel across the minds of individuals at different locations and epochs. Such analyses will also enable researchers to identify the factors that catalyze or hinder cultural diffusion of ideas (Legare, 2017).

In the following sections, we define culture, creativity, and innovation. Next, to illustrate the utility of performing multilevel, multiprocess analyses, we provide a selective review of the literature on cultural differences in creativity/innovation, as well as the recent research on the creative benefits of multicultural experiences and cultural diversity. Finally, we shift the focus to historical variations and geographic diffusion of inspiring ideas and discuss how a cultural-psychological perspective can advance research on the reciprocal influence of culture and creativity.

KEY CONCEPTS

Culture

There are many definitions of culture. In this chapter, we adopt one that highlights the reciprocal influence of culture and creativity/innovation. Specifically, we define “culture” as a knowledge tradition that consists of a loosely organized constellation of socially transmitted ideas and practices (Chiu & Hong, 2006). These ideas and practices are embodied, enacted, or instituted in everyday life (Fryberg & Markus, 2007). According to this definition, a culture can be a national culture, a religious culture, a

disciplinary culture, or any other shared and inheritable knowledge tradition (Chiu, Kwan, & Liou, 2013a, 2013b). Although, in cultural psychology, researchers often use society as a proxy for culture, we find it useful to distinguish culture from society. Whereas “culture” refers to a set of socially transmitted meanings or information that is imperfectly shared within a group and passed on across generations (e.g., Christianity, Confucianism), “society” refers to a collection of individuals and groups, their relationships, and their institutions (e.g., European societies, Asian societies; Kashima & Gelfand, 2012).

Through sharing and reproduction, cultural knowledge and practices are transmitted horizontally from one cultural member to another, and vertically from one generation to the next. People may accept and imitate the transmitted ideas or practices. The transmitted ideas or practices may also trigger a creative process, leading to progressive modifications and refinements of the original ideas and practices (Gabora, 2018; Legare, 2017).

Comparative anthropologists (e.g., de Waal, 1999) discovered that apes are also capable of generating new practices (e.g., some apes build a cover on their nest during bright sunshine to provide shelter from the sun) and imitating the behaviors of the innovators. However, only humans are able to cumulate modifications of their invention over time. For example, once the wheel was invented, the new generations built on it and invented the carriage, then the motor vehicle. This unique human process is referred to as “ratcheting.” Through ratcheting, sophisticated cultural knowledge and complex cultural practices *evolve over time* (Tomasello, 2001).

Creativity/innovation enables cultural evolution. Meanwhile, culture constrains the creativity/innovation processes (Chiu & Kwan, 2010). For example, existing knowledge in the culture is an important source of inspiration. Conventional knowledge in the culture also provides the reference for evaluating the originality or novelty of new ideas; what is new is relative to what is already known and widely accepted. Finally, some cultural processes (the motivation to protect the “purity” or “integrity” of a cultural tradition when it is under contamination threat) can slow down or even stop innovation-driven cultural changes (Chiu, Gries, Torelli, & Cheng, 2011; Chiu & Kwan, 2016).

Creativity/Innovation

“Creativity” refers to the capability or act of conceiving something novel and useful (Amabile, 1996). What is creative must be original *and* useful: By this definition, a novel application of an existing idea is a creation. In business, a new business model that has been applied to market an existing product successfully is considered creative. In contrast, a common and useful idea is practical but not creative, and a novel but useless idea is bizarre rather than creative.

As mentioned earlier, researchers have differentiated between Big-C and small-c creativity. “Big-C creativity” refers to the creativity of gifted and eminent people (e.g., Albert Einstein, W. A. Mozart), whose creative productions are widely known but rare in the culture (Gardner, 1993). “Small-c creativity” is the everyday creativity displayed by ordinary people (e.g., the creation of a new recipe; Amabile, 1996).

Situational factors play a crucial role in both small-c and Big-C success. For example, small-c research has shown that everyday creativity is the extraordinary outcomes of ordinary psychological processes evoked by the situation. Likewise, psychological studies of Big-C creativity have focused on common psychological processes that underlie eminence and genius. An example is Howard Gardner’s (1993) study of the creative minds of Freud, Einstein, Picasso, Stravinsky, Eliot, Graham, and Ghandi. This work has demonstrated that even for the creative accomplishments of geniuses, circumstance has played an indispensable role in creative success.

In addition, both Big-C and small-c creativity typically involve extension of the conceptual boundaries of existing concepts (Ward, Patterson, Sifonis, Dodds, & Saunders, 2002). An example is the creative extension of the principles of hydrodynamics when they are applied to explain dynamic processes in psychoanalysis. Conceptual extension often results from the combination of seemingly unrelated concepts (e.g., psychology + physics → psychophysics; cultural psychology + cognitive neuroscience → cultural cognitive neuroscience; Wan & Chiu, 2002).

Innovation builds on creativity; “innovation” refers to the process of turning a creative idea into a new and significantly improved product, process, business model, management practice, or external relation (Organization for Economic Cooperation and Development [OECD], 2010).

A major concern in innovation research is how innovation outputs can be categorized. Innovation researchers have differentiated between incremental and transformational innovation (Pavitt, 1991). “Incremental innovations” bring improvements to existing ideas or products by adding to them new features, extensions, variations, or complements. In contrast, “transformational innovations” refer to breakthroughs, frame-breaking, or disruptive innovations. Compared to incremental innovations, transformational innovations have more profound knowledge and economic impacts.

Recent cognitive neuroscience evidence shows that the brain responds differently to transformational and incremental innovation products. When people encounter a new product, they typically ask two questions: What is it? And how to use it? Different brain systems are responsible for semantic knowledge construction (the conceptual pathway) and for retrieving knowledge of the acquired skills necessary for performing the actions associated with using the product (the motor pathway). Transformational innovations evoke more activation in the conceptual pathway for object representation, whereas incremental innovations evoke more activation in the motor pathway (Huang, Chiu, & Luo, 2016). Because incremental innovations differ only slightly from existing products, the users spontaneously transfer the skills acquired for operating similar existing products through an analogy transfer strategy (this new invention can be used like an existing product). Hence, incremental innovations evoke more activation in the motor pathway. In contrast, transformational innovations differ substantially from any existing products and are not associated with directly transferrable practical experience. Understanding what this new invention is relies primarily on the semantic properties of the new invention’s functions. Thus, transformational innovations evoke more activation in the conceptual pathway.

The Global Innovation Index (GII; Cornell University, INSEAD, & WIPO [World Intellectual Property Organization], 2013) is a comprehensive measure of the levels of annual innovation inputs and outputs of a society. The index includes three subindices of knowledge outputs. First, the Knowledge Creation subindex measures the fluency of knowledge creation, which is reflected in the quantity of new ideas, products and services created within a certain period of time, controlling for the population sizes of the

societies¹ (Dakhi & de Clercq, 2007). Sample indicators of Knowledge Creation fluency are the number of patents applied for and the number of science and technology articles published by the residents of a society. Second, Knowledge Impact measures the local economic impact (e.g., increase in labor productivity, new firm density, volume of high-tech production, and personal income per capita) the new products and services have generated, as well as the improved productivity resulting from new processes of managing inventories and logistics (Mairesse & Mohnen, 2002). Finally, Knowledge Diffusion captures the global influence the new products and services have produced in the innovation industry (e.g., Dakhi & de Clercq, 2007). Innovation outputs that have global influence (e.g., Google and Facebook) are those that have been adopted widely outside of their sites of origin.

Stages of Creativity/Innovation

The creativity/innovation process consists of several iterative stages (Chiu & Kwan, 2010). At the idea generation stage, one or more ideas are generated. At the idea selection and editing stage, competing ideas are evaluated and selected for further refinement and development. At the stage of idea marketing and adoption, the innovative work is presented to one or more audiences for adoption consideration. At each stage of creativity/innovation, the agent may be an individual, a team, or an organization. The same or different agent(s) may participate at different stages of creativity/innovation.

As summarized in [Table 26.1](#), different cultural-psychological processes are involved at the different stages of innovation and creativity. At the stage of idea generation, the goal is to create ideas that are novel and useful. There are at least two reasons why culture is relevant at this stage. First, as mentioned earlier, what is novel is relative to the conventional knowledge in the culture. For example, an established finding in sociology and social psychology is that an opinion can be infectious and spread across spatially connected agents in a social network through social influence. This finding is also well supported in geography. According to the first law of geography, everything is related to everything else, but near things are more related than distant things (Tobler, 1970). A recent discovery in epidemiology is

that the diagnosis of autism (a genetically transmitted disease) also spreads across a social network in the same way an opinion does (Liu, King, & Bearman, 2010). This finding is considered revolutionary in epidemiology. This example shows that a discovery may be considered incremental in one knowledge tradition but frame breaking in another one, depending on how much it deviates from the well-accepted premises and past knowledge in the knowledge tradition.

TABLE 26.1. Cultural Processes at Different Stages of Creativity/Innovation

Stage of creativity/innovation	Cultural processes
Idea generation	<ul style="list-style-type: none"> • Conventional knowledge provides a reference for evaluating the originality of new ideas/practices • Conventional thoughts and habitual thinking processes create mental blocks in creative idea generation and problem solving
Idea selection and editing	<ul style="list-style-type: none"> • Assumed normative preferences bias selection of ideas for refinement and further development
Idea marketing and adoption	<ul style="list-style-type: none"> • Actual normative preferences determine the likelihood of market acceptance of new ideas/practices

Second, conventional knowledge can create mental blocks in the generation of novel ideas. In one study (Ward et al., 2002), participants were asked to produce creative drawings of aliens. In this study, most extraterrestrial creatures generated by the participants contained human features (e.g., eyes, mouths, limbs). This happened because these features are typical exemplars of the physical features of living things that are easily retrievable from memory. What distinctive regional cuisines are created in a culture is also related to the foods that are particularly accessible both physically and mentally to people in a certain region (Gebremariam et al., 2017; Rozin, Ruby, & Cohen, [Chapter 17](#), this volume). Creative idea generation often requires extra mental effort or multicultural experiences to overcome the inhibitory effects of habitual thoughts and thinking processes on creative idea generation, and to access and use cognitively less available exemplars in creative problem solving (Ip, Chen, & Chiu, 2006; Leung & Koh, [Chapter 21](#), this volume). For example, Asian Americans were more

creative in developing new dishes using a given set of ingredients only when they were motivated to combine Asian and American cultures, *and* when both Asian and American ingredients were available (Cheng, Sanchez-Burks, & Lee, 2012).

At the idea selection and editing stage, ideas that are perceived to have a higher chance of being accepted by the adopters have higher chances of being selected for further development and refinement (Chiu & Kwan, 2010). Accordingly, the perceived or assumed descriptive norms in the culture will bias idea selection (Li et al., 2013). For example, Koreans and Taiwanese expect others in their culture to favor ideas that are mildly original but very practical rather than those that are highly novel and only slightly useful, whereas the Americans and the Dutch expect others in their culture to have the opposite preferences. Consequently, highly practical ideas are more likely to be selected in Korean and Taiwanese contexts, whereas highly original ideas are more likely to be selected in American and Dutch contexts, although, when asked to generate ideas in private (when cultural norms are not salient), the four cultural groups are able to produce equally original ideas (Bechtoldt, De Dreu, Nijsta, & Choi, 2010). We return to this phenomenon when we discuss cultural differences in creativity/innovation.

At the idea marketing and adoption stage, the actual descriptive norms in the culture, which reflect both the users' actual preferences and the utility of the idea to the community, will determine how likely innovative works will succeed in the market (Chiu & Kwan, 2010). Innovative works that appeal to many people or provide novel solutions to common problems in the society are more likely to be accepted.

CULTURAL DIFFERENCES IN CREATIVITY AND INNOVATION

Institutional Support for Innovation

It is hard to overlook regional variations in innovation outputs. According to the GII (Cornell University et al., 2013), countries in North America and Western Europe have higher performance in innovation outputs than do

countries in other continents. In 2013, the 10 societies with the best performance in innovation outputs are Western societies (Switzerland, the Netherlands, Sweden, the United Kingdom, Malta, Luxembourg, Iceland, Finland, Israel, and Germany). Some Asian societies also occupied high ranks (11th to 30th) in innovation outputs in 2013. They are China, the Big Dragon (Japan), and the Little Dragons (Hong Kong, Singapore, South Korea).

Societies that have the best innovation performance have high income and rich human resources to support innovation. Moreover, when the income (measured by gross domestic product [GDP]) per capita and the quality of human capital (measured by the level and standard of education and research activity) of a society increase, its innovation outputs also improve. However, wealth does not fully explain society variations in innovation performance. For example, the United Arab Emirates, a petroleum exporting country, has high GDP per capita (over US \$65,000). However, its innovation performance (measured by the amount of innovation outputs relative to innovation inputs) is low (ranked 104th in the 2017 GII Report). Moreover, the beneficial effects of income and human capital on innovation performance are limited to having a greater number of new ideas, products, and services created (as measured by the Knowledge Creation subindex of the GII; Kwan & Chiu, 2015).

It is not surprising that societies that have invested more heavily in human capital would produce a greater amount of innovation outputs. To go beyond fluency in knowledge creation, societies need to construct and make available an institutional framework to support innovation. “Institutional support for innovation” refers to the extent to which a society has established legal and political institutions, and good governance to protect freedom of expression and the innovators’ proprietary rights to their intellectual and financial properties (Chiu & Kwan, 2018). Societies that have better institutional support for innovation, in addition to having rich financial and human resources, are better at producing innovations with high local economic impact (as measured by the Knowledge Impact subindex of the GII; Kwan & Chiu, 2015). Finally, having good institutional support is indispensable for creating knowledge and technology with global influence (as measured by the GII Knowledge Diffusion Index; Kwan & Chiu, 2015). Some countries (e.g., Brazil, Russia, India, and China) have

experienced very rapid economic growth recently. Although the volume of knowledge and technological innovations in these countries has increased, most of these innovations are incremental in nature. For example, China has made heavy investment of its rapidly expanding national revenue in various global talent recruitment schemes. This investment has led to an impressive increase in knowledge creation, but it has thus far had limited beneficial effects on its development of transformational innovation with global impact (Chiu, Liou, & Kwan, 2016). Researchers have empirically linked the lack of progress in China's transformational innovation despite China's investment in human capital to the lack of institutional support for innovation in the country (Chiu et al., 2016; Zweig & Wang, 2013).

One implication of this finding is that wealth and talents are of critical importance for innovation performance. Wealth and talents by themselves are sufficient for increasing the volume of innovative outputs, although they are not sufficient for developing frame-breaking and high-impact innovations. To develop transformative innovations, societies also need to establish institutional support for innovation.

These findings further illustrate the qualitative differences between incremental and transformational innovation. Transformational innovations are not just more profound innovations compared to incremental ones. Instead, transformational and incremental innovations are distinct types of innovation supported by different institutional factors. In one study, Dunlap-Hinkler, Kotabe, and Mudambi (2010) classified new applications to the U.S. Food and Drug Administration into incremental innovations (innovations in the form of new features, extensions, variations, or complements to an existing product line) and breakthroughs (innovations that start a new cycle of technological change). The result of this study showed that pharmaceutical companies that had a successful track record in generic incremental innovations had *fewer* breakthrough innovations, possibly because the climate and reward system in these firms favor exploitation of existing knowledge rather than risk taking and exploration of new knowledge.

Innovation researchers have distinguished between the presence of institutions that support innovation (institutional support) and "institutional trust," which refers to the extent to which people in the society believe that its institutions are trustworthy and will act with predictability

and goodwill. People tend to trust their institutions only when there are established legal and political regulatory institutions. However, even in societies with established regulatory institutions (Indian societies), people may not trust their institutions. In addition, the level of institutional trust in the same country may change over time. For example, Wall Street scandals can lead to trust crises in U.S. financial institutions. Likewise, scandals of political leaders can cause citizens' trust in a democratic country's political institutions to crumble.

Researchers have debated how institutional support and institutional trust jointly influence a society's innovation performance (Chiu & Kwan, 2018). Three different hypotheses are outlined below.

The first hypothesis, the *mediation hypothesis*, states that institutional support for innovation engenders trust in the institutions, which in turn facilitates formation of new network ties and knowledge sharing, leading to higher quantity and quality of innovation outputs (Dixit, 2004; Granovetter, 1985). From this perspective, institutional support for innovation stimulates innovation through the indirect effect of increased trust in the institutions. Accordingly, institutional trust should mediate the effect of institutional support on innovation performance.

The second hypothesis, the *mutual reinforcement hypothesis*, is that institutional trust evolved in societies that were ruled by egalitarian political institutions in the distant past (Tabellini, 2008). In these societies, institutional trust is a form of cultural capital and can reinforce the positive effect of institutional support for innovation on a country's innovation output by improving coordination and reducing transaction costs in social exchanges, rendering institutional regulation more efficient (Luhmann, 1979). Meanwhile, the presence of strong institutional support reduces the risks of trusting the institutions (Cook, 2005; Cook, Hardin, & Levi, 2005). According to this view, institutional support and institutional trust should have a positive interaction effect on innovation performance; that is, institutional support benefits innovation performance more when institutional trust is high (vs. low). Likewise, institutional trust improves innovation performance more with the presence of strong institutional support.

The third hypothesis, the *compensation hypothesis*, states that institutional trust benefits innovation performance only when institutional

support is absent in the society (Peng, 2003; Tan, Tang, & Veliyath, 2009). In societies with well-established institutional support for innovation, innovation flourishes, because there is good governance, and adequate protection and incentives to support innovation, independent of how much people trust these institutions. Trust in institutions becomes important only in societies in which institutional support for innovation has not been firmly established. In these societies, trust in the institutions is critical to innovation performance. According to this hypothesis, there should be a negative interaction effect of institutional support and institutional trust on innovation performance. Thus, either institutional support or institutional trust is sufficient.

In summary, although the availability of talents predicts the volume of innovation production in a society, it does not guarantee that the innovation outputs will have high knowledge and economic impact. Both talents and availability of institutional support for innovation are necessary for creating high-impact innovation. Institutional trust is another variable that may explain societal differences in innovation performance. An interesting future research direction is to understand how the presence of supportive institutions, and trust in these institutions, jointly affect a society's innovation performance.

Cultural Values

As mentioned earlier, many Western societies and some Asian societies (China, Japan, Singapore, Hong Kong) have impressive performance in innovation. Are variations in innovation across societies related to cultural values? [Table 26.2](#) shows the zero-order correlations between innovation output (GII; Cornell University et al., 2013) and the Hofstede (Hofstede, Hofstede, & Minkov, 2010) value dimensions across more than 60 societies. Societies with higher levels of innovation output are those that value individualism, long-term orientation, indulgence, and less power distance. Apparently, innovative societies tend to be those that prioritize individual goals (individualism), being future-oriented (long-term orientation), freedom of speech and personal control (indulgence), and egalitarianism (less power distance).

TABLE 26.2. Prediction of Innovation Output from Values across Countries

	Zero-order correlation	Unstandardized regression weight
Intercept		27.52
GDP per capita		0.28 (0.12)*
Power distance	-.52***	0.05 (0.13)
Individualism	.63***	0.33 (0.11)**
Uncertainty-avoidance	-.25*	-0.11 (0.08)
Long-term orientation	.38***	0.43 (0.10)***
Masculinity	-.09	-0.13 (0.09)
Indulgence	.25*	0.25 (0.11)*

Note. $N = 61$; * $p < .05$; ** $p < .01$; *** $p < .001$.

When all six Hofstede values and GDP per capita were entered into a multiple regression analysis, the two value dimensions that were strongly associated with innovation output were individualism and long-term orientation. The effect of power distance became nonsignificant, probably because of its strong negative association with individualism. According to Hofstede et al. (2010), “individualism” refers to the extent to which ties between individuals in the society are loose, such that an individual in the society is expected to prioritize the goals and welfare of him- or herself and his or her immediate family. Western societies tend to value individualism more than other societies. “Long-term orientation” refers to the extent to which a society values virtues that are oriented toward future rewards, such as perseverance and thrift. Chinese societies (including Singapore, Taiwan, Hong Kong, China) value long-term orientation more than other societies.

Innovation may occur through exploration of new ideas or exploitation of current knowledge. Although both individualism and long-term orientation predict better innovation performance, individualism may play a more important role in supporting exploration of ideas, because individualism privileges individual expression and personal uniqueness, and encourages generation of unique and novel ideas. In contrast, long-term orientation may play a more important role in supporting exploitation of current knowledge, because societies with long-term orientations tend to take a more pragmatic approach and emphasize strategic planning in problem solving.

The mainstream value orientation in a society may influence its preferred strategy to develop creativity and innovation. Western societies may favor the individualism-oriented approach, whereas Chinese societies may favor the long-term-oriented approach. Consistent with this idea, in a cross-cultural study of lay theories of creativity, Loewenstein and Mueller (2016) found that Americans used a narrow span of novelty-related attributes (*breakthrough*, *surprise*, and *potential*) to characterize a creative product or process. Americans consider a non-novel product or process that is feasible, easy to use, and appealing in a mass market to be noncreative. In contrast, aside from the novelty attributes, Chinese also use attributes such as *easy to use*, *feasible*, and *for a mass market* to characterize a creative product or process.

Individualism also plays a particularly important role in supporting the generation of creative outputs. Bendapudi, Zhan, and Hong (2018) differentiate between two types of innovation outputs: (1) knowledge and technology outputs and (2) creative outputs. Knowledge and technology outputs are knowledge and applications resulting from scientific and technological research, whereas creative outputs are products, goods, and services in the creative industries (Stupples, 2014). Having high-quality education may be enough to advance scientific knowledge and technology. However, a culture that privileges individualist values is also needed to drive creative outputs. Consistent with this idea, the results of the Bendapudi et al. (2018) study show that irrespective of whether individualist values are prioritized in a society, as long as a society provides high-quality education, the society tends to have high performance in knowledge and technology outputs. However, quality of education predicts performance in creative outputs only in societies that also emphasize individualist values. This finding implies that societies that seek to foster creative cultural industries, aside from investing in their human resources, may also need to develop a more individualist culture.

Cultural Traits or Norms?

However, the presence of cross-cultural differences in innovation performance and innovation-related values does not imply that, compared

to each other, Westerners are more original creators, whereas Asians are more practical innovators. In fact, cross-cultural studies of creative performance at the individual level have failed to find consistent evidence for differences between Westerners and Easterners in creativity (Erez & Nouri, 2010; Morris & Leung, 2010). Instead, as we describe below, differences in creative behaviors arise not from the personal dispositions of Westerners and Easterners, but from the different cultural norms in Western and Eastern societies.

Some studies (e.g., Niu, Zhang, & Yang, 2007) have indicated that individuals from Western cultures (United States, Europe) outperform individuals from Asian cultures (e.g., China, Japan) in standardized tests of creativity. However, results from these studies are often difficult to interpret because of measurement equivalence issues and the lack of culture fairness in creativity assessment. For example, many standardized tests of creative performance were developed in the West and sometimes administered to non-Western participants in English (Zhou & Su, 2010). There are also studies that have failed to find consistent cross-cultural differences in individual performance on creativity tasks. For example, in one study (Saeki, Fan, & Dusen, 2001), Americans and Japanese completed the Figural test of the Torrance Tests of Creative Thinking. Compared to Japanese, Americans produced more abstract and elaborate ideas, but the two groups did not differ in the number of ideas generated, and the ideas generated by the two groups were equally original. In another study (Zha, Walczyk, Griffith-Ross, Tobacyk, & Walczyk, 2006), Americans outperformed the Chinese on divergent thinking, but personal endorsement of individualism did not mediate the group difference in performance.

If cultural variations in creativity/innovation do not originate from cultural differences in personal values or attributes, researchers who seek to explain cultural differences in creativity and innovation must look elsewhere for answers. Some researchers (Chiu & Kwan, 2010; Erez et al., 2010; Morris & Leung, 2010) have offered a normative explanation of the cultural differences. According to one version of the norm explanation (Li et al., 2013), people are aware of the normative preferences in their culture. For example, Americans know that other Americans value originality more than the long-term use value of a new idea, whereas the Chinese know that other Chinese prize long-term use value more. When they perform a test of

creativity *alone*, cultural norms are not salient. Thus, in this assessment context, Americans and Chinese perform equally well on the test, and their responses do not differ in originality or use value. However, when they perform the same creativity task in a group context or when they need to decide which idea they would select for further development, the assumed normative preferences in the culture are salient, and individuals tune their behaviors in the direction of the cultural norms. Under these circumstances, Americans tend to generate and select original ideas, whereas Chinese tend to generate and select practical ones.

Consistent with this norm explanation, Nouri, Erez, Rockstuhl, and Ang (2008) found that Singaporeans and Israelis performed equally well on a creativity test when they took the test alone. However, when they took the test in groups, the Israeli teams were more original than the Singaporean teams. In contrast, the Singaporean teams elaborated more on the appropriateness of each idea they generated.

In another study, Bechtoldt et al. (2010) asked Dutch and Korean student teams to generate new ideas to improve university teaching. Dutch students generated more original ideas when they were (vs. were not) instructed to do their best. In contrast, Korean student teams generated more useful ideas when they were asked to do their best. The instruction “to do one’s best” induced the motivation to meet normative expectations. When the Dutch participants were experimentally induced to perceive usefulness to be the prevalent norm of creativity in the group, the instruction “to do their best” in a team creativity task increased the usefulness but not the novelty of their ideas.

Liou and Lan (2018) also found that when instructed to generate new design ideas alone, Americans and Taiwan Chinese generated equally original ideas. However, when American and Taiwanese teams were instructed to discuss the ideas generated by the individual team members and selected some ideas for further development, the ideas selected by the American teams were more original than those selected by the Taiwanese teams. Moreover, the ideas discarded by the Taiwanese teams were more original than those discarded by the American teams. The normative explanation of cultural differences in creative performance is consistent with the recent neuroscience findings that heightened neural reaction (event-

related potentials) to norm violations inversely predicts creative outputs (Mu, Kitayama, Han, & Gelfand, 2016).

In addition, societies also vary in motivational norms related to creative endeavors. For example, Cheng and Hong (2017) have found that the cultural norm of *Kiasu* (a Singaporean indigenous construct corresponding to fear of losing out) induced a prevention orientation toward creativity tasks, thereby hampering Singaporean participants' creativity performance. By the same token, Leung and colleagues (2018) revealed that the middle-ground thinking style, which is often endorsed by Chinese and Singaporeans, reduced the feeling of conflict toward paradox, thus resulting in less creative solutions in resolving paradoxical problems.

Summary

Due to differences in cultural values, some societies (e.g., Western societies) follow an individualism-oriented approach to creativity/innovation. Individuals in these societies expect that others would evaluate the level of creativity of a new idea by its originality only. When this normative expectation is rendered salient in the context, individuals tend to generate and select original ideas when performing creativity tasks. These societies often have higher performance in creative outputs and in original and transformational innovations.

In contrast, some societies (e.g., Taiwan, Singapore) follow a long-term-oriented approach to creativity and innovation. People in these societies expect others would value long-term benefits of a new idea when they evaluate its level of creativity. When this normative expectation is made salient in the context, individuals tend to generate and select ideas that can be applied to deal with the challenges of the present and the future. These societies value both originality and usefulness in idea selection. In addition, societies also vary in their motivational norms toward creativity, which in turn contributes to cross-national differences in creativity performance.

MULTICULTURAL EXPERIENCE, CULTURAL DIVERSITY, AND CREATIVITY/INNOVATION

Creative Benefits of Multicultural Experiences

We now turn to the issue of whether multicultural experience and cultural diversity can enhance creativity and innovation. In an interview given to Salon (www.salon.com) in 2002, Kishore Mahbubani, Singapore's former ambassador to the United Nations and author of *Can Asians Think?*, said, "I'm curiously a child of both the East and the West and the only advantage this provides is that I can actually enter the mental universes of Asia and of the West. By being able to do so, I can see that there are two different mental universes." Do multicultural experiences also confer creative benefits? Initial research evidence shows that individuals with rich multicultural experience are able to generate a greater diversity of ideas, as well more original ones, in standardized measures of creativity (Leung, Maddux, Galinsky, & Chiu, 2008). These individuals are also prepared to borrow ideas from foreign cultures in creative problem solving (Leung & Chiu, 2010).

Exposure to multicultural experience places ideas from different cultures in cognitive juxtaposition and increases awareness of cultural dissimilarities (Chiu, Mallorie, Keh, & Law, 2009), which in turn evokes unpleasant cognitive dissonance. The motivation to reduce cognitive dissonance motivates people to combine seemingly incompatible cultural ideas into a novel concept (Cheng & Leung, 2013; Cheng, Leung, & Wu, 2011). As a result, the conceptual boundaries of both mother concepts are extended.

Subsequent studies indicated that multicultural experiences have greater creative benefits for some people some of the time. For example, cultural immersion through academic exchanges and expatriate assignments is more likely to have creative benefits than do short-term foreign travels or sojourns (Maddux & Galinsky, 2009). People who are more open to experience benefit more from multicultural experience (Leung & Chiu, 2008), even when they are worried that extensive cultural borrowing may cause erosion of their own culture (Chen et al., 2016). The preparedness to learn from foreign cultures also enhances the creative benefits of multicultural experiences (Maddux, Adam, & Galinsky, 2016). Compared to people who believe that cultures are distinctive, separate legacies, those who believe that cultures are evolving interactive systems tend to be more receptive to cultural borrowing and cultural mixing (Cho, Morris, & Dow, 2018; Cho, Morris, Slepian, & Tadmor, 2017).

The potential creative benefits of multicultural experiences are curtailed when people are led to focus on cultural similarities, because registration of cultural similarities obscures cultural differences and complementarity, and removes the need to integrate seemingly incompatible ideas to create novel conceptual combinations (Cheng & Leung, 2013; Peng & Xie, 2016). In addition, the potential creative benefits of multicultural experiences are reduced when people are motivated to defend the purity and continuity of their culture (Cho et al., 2017; Yang, Chen, Xu, Preston, & Chiu, 2016). Such defensive motivation is evoked when people have strong patriotic sentiments (Cheon, Christopoulos, & Hong, 2016) and feel that mixing of cultures has caused contamination or erosion of one's culture (Cheon et al., 2016; Yang et al., 2016). The experience of existential anxiety also increases people's reliance on the purity and continuity of one's culture as a worldview defense. Thus, when people experience an existential threat, they also tend to resist cultural borrowing in creative problem solving (Torelli, Chiu, Tam, Au, & Keh, 2011).

Creativity/Innovation of Culturally Diverse Work Teams

The creative benefits of multicultural experience may incite an optimistic expectancy that cultural diversity in a work team will also improve the team's creative performance. There are theoretical reasons for being optimistic. First, a culturally diverse team consists of members who possess insider knowledge of different cultures and can therefore provide nonredundant intellectual resources for creative problem solving. The presence of divergent cultural perspectives in the team also raises members' awareness of the alternative approaches to solving the same problem in different cultures (Han, Peng, Chiu, & Leung, 2010; Proctor et al., 2011). Although apparent inconsistencies among dissimilar cultural perspectives can cause cognitive conflicts, evidence from several laboratory experiments and field studies shows that successful resolution of these conflicts through creative synthesis of seemingly incompatible ideas can improve creative performance of the team (De Dreu, 2010; Schulz-Hardt, Broadbeck, Mojzisch, Kerschreiter, & Frey, 2006) and even lead to frame-breaking innovations (Dunlap-Hinkler et al., 2010).

There is also evidence that the extent of cultural diversity predicts higher levels of creativity and innovation in organizations. For example, in their study of successful patent applications of pharmaceutical innovations from 98 firms filed at the U.S. Food and Drug Administration between 1992 and 2002, Dunlap-Hinkler et al. (2010) found that frame-breaking innovations are more likely to come from pharmaceutical companies that have benefited from cultural diversity through formation of an alliance with another company in a foreign country. In another study, Nathan and Lee (2013) found that firms with higher levels of immigrant diversity among its owners and partners were more successful in producing innovative products or services, modifying existing products, introducing new equipment into their operations, and inventing and implementing new ways of working. Likewise, Hewlett, Marshall and Sherbin (2013) found that firms with culturally diverse leadership are more successful in capturing a new market. In Germany, the level of cultural diversity of knowledge workers in a research-and-development (R&D) firm predicts higher innovation performance in the firm (Niebuhr, 2010). In addition, Hunt and Gauthier-Loiselle (2010) showed that in the United States, between 1940 and 2000, every percentage-point increase in immigrant college graduates' population share was accompanied by a 9–18% increase in number of patents per capita.

However, cultural diversity does not always enhance team creativity. It does when the following conditions are met: First, team members are aware of how expertise and preferences are distributed in the group (Hollingshead, Gupta, Yoon, & Brandon, 2012; Huber & Lewis, 2010). Second, team members believe that cultures can grow through learning from other cultures (Chiu et al., 2013a). Third, team members are willing to express their personal views and believe that there are mechanisms for managing potential cognitive conflicts constructively (Tjosvold, 1998). Finally, the team is more creative if it is not pressured to have closure on the problem it attempts to solve (Chirumbolo, Livi, Mannetti, Pierro, & Kruglanski, 2004; Chirumbolo, Mannetti, Pierro, Areni, & Kruglanski, 2005).

Cultural diversity may also have adverse effects on team creativity. When team members from different cultures follow different norms of problem solving and social interaction, cognitive and relationship conflicts may arise, resulting in performance impairment (De Dreu & Weingart, 2003).

Conflicts are particularly likely to arise when there is a fault line in the team. A fault line is formed when team members perceive a clear simultaneous alignment of multiple demographic, cultural, functional, and psychological characteristics across members (Thatcher, Jehn, & Zanutto, 2003).

Before a fault line is formed in a culturally heterogeneous team, there may be no associations between cultural membership and other characteristics, including the beliefs, values, and preferences of the individual members. Members treat disagreement within the team as disagreement between individuals rather than as cultural conflicts. Once a fault line has developed in the team, the team is divided into relatively homogenous subgroups based on group members' cultural memberships and their associated cultural attributes (Lau & Murnighan, 1998), and members may support or fight against one another because of their shared cultural membership. Under such circumstances, disagreement within the work team may develop into a cultural conflict (Han et al., 2010; Jehn, Bezrukova, & Thatcher, 2007).

Fault lines often develop in multidisciplinary teams. Most established disciplines have their distinctive cultures. Members of an established discipline have consensus on the set of criteria used for evaluating the validity and value of knowledge. They also agree to use similar metaphors or paradigms to guide their practices (Chiu et al., 2013b). Disciplinary culture is taught or passed down to newer generations of practitioners through disciplinary socialization (Guimond, 1999; Guimond & Palmer, 1996). When members of two disciplines with markedly different knowledge traditions (e.g., engineering and marketing) collaborate, a fault line may develop, and members of the two disciplines often complain about each other's intellectual limitations (Workman, 1997). Research has also revealed intense cognitive and relationship conflicts between disciplinary groups in some innovation teams (Amason & Schweiger, 1997; Northcraft, Polzer, Neale, & Kramer, 1995).

Consistent with the idea that cultural diversity can increase team creativity as long as a fault line has not developed in the team, Ozgen, Nijkamp, and Poot (2013) found that in the Netherlands, firms with high innovation performance tend to be those that employ foreign workers from many different countries, but only a few employees from each country. In these firms, the local employees are not threatened by potential outgroup

domination or competition and are therefore more willing to seek inspirations from the new ideas of the foreign workers. In contrast, firms with lower levels of innovation performance tend to be those that employ a large percentage of foreign employees from the same cultural group. In these firms, the local employees may feel threatened by outgroup domination and competition. Perceived intergroup competition may lead to conflicts between the local and foreign cultural groups.

The Cultural Deficit Hypothesis

If coordination of individuals in culturally diverse teams is challenging, coordination of culturally diverse groups in a multicultural society is even more so. There are competing hypotheses regarding the effect of cultural diversity on creativity and innovation at the society level. The *diversity dividend theory* (Gerring, Thacker, Lu, & Huang, 2015) holds that cultural diversity is essential to the development of creativity in a society. In contrast, the *diversity debit hypothesis* (Gerring et al., 2015) holds that high levels of cultural diversity in a society are often associated with severe ethnic and linguistic fractionalization. Ethnolinguistic fractionalization increases the risk of civil strife and internal conflicts, which harms economic, social, and technological development. For example, ethnic and linguistic divisions inside a society can create barriers to communication and increase factions, rivalries, and internal conflicts (Easterly, 2001; Easterly & Levine, 1997). In contrast, cultural homogeneity can foster interpersonal trust (Zak & Knack, 2001).

To understand the relationship between cultural diversity and innovation performance at the societal level, it is important to make a distinction between ethnolinguistic and ideological-religious diversity. Societies with greater amounts of ethnolinguistic diversity have poorer innovation performance (Zhan et al., 2015; Kwan & Chiu, 2018). However, the extent of religious diversity in a society is unrelated to its innovation performance. Furthermore, the extent of ideological diversity or diversity in cultural values in a society is positively associated with its innovation performance, as long as the level of ethnic polarization in the society is low (Zhan et al., 2015).

Although cultural diversity per se does not foster innovation, positive interdependence and interactions between cultures do. A meaningful distinction can be made between ethnolinguistic fractionalization (which is often measured by the extent of ethnolinguistic heterogeneity within a society) and cultural complexity, which reflects the frequency and intensity of intercultural interactions. Although ethnolinguistic fractionalization can sometimes lead to cultural clashes and hurt innovation, frequent positive intercultural interactions within a society and between societies can facilitate innovation. Economic complexity is an established measure of cultural complexity measured through a country's economic production characteristics. According to Hidalgo and Hausmann (2009), for a complex society to exist and to sustain itself, people who engage in knowledge production professions (design, technology, marketing) must be able to interact and combine their knowledge to make products. Economic complexity of a country is defined and measured by its economic capacity to possess and combine knowledge from different countries. Cross-cultural research evidence shows that the level of economic complexity of a society has a strong positive relationship with its innovation output, after controlling for GDP per capita, total health expenditure per capita, population size, and gross expenditure on R&D (Kwan & Chiu, 2018).

Summary

Individuals with diverse cultural experiences tend to be more creative. They are also more cognitively prepared to retrieve unconventional knowledge and synthesize seemingly unrelated ideas to form creative ones in creative problem-solving tasks. The potential creative benefits of multicultural experience are more likely to be actualized when individuals believe that cultural borrowing and intercultural learning can benefit the growth of the individual and one's own culture. Multicultural experience may not enhance creativity if, for various reasons (e.g., under epistemic, symbolic, or existential threats), individuals are motivated to defend the purity and survival of their culture by resisting cultural borrowing and intercultural learning.

Cultural diversity in a work team can enhance creativity as long as a cultural fault line has not developed in the team. It is possible to mitigate the adverse effects of cultural conflicts on team creativity by increasing team members' awareness of the complementary cultural expertise inside the team and developing ways to promote intercultural learning and resolve cognitive conflicts constructively.

At the societal level, the extent of ethnolinguistic diversity can lead to ethnolinguistic fractionalization and hence hurts the society's innovation performance. Although ethnolinguistic diversity per se may have negative effects on innovation, having more opportunities for positive interdependence and interactions between cultures is positively associated with higher levels of innovation output.

HISTORICAL VARIATIONS IN CREATIVITY AND INNOVATION

“Can Asians think?” That was the question Kishore Mahbubani (2002) posed in his book. Mahbubani was interested in the question of how Asian societies, which were once major movers and shapers of global civilization, lost their leading edge to Western societies. In an interview with *Salon.com*, Mahbubani said “In the year 1000 the most successful, the most flourishing and the most dynamic societies in the world were Asian. Europe was still struggling out of the Middle Ages and North America hadn't been discovered. One thousand years later you get the exact reverse of that: the most dynamic and flourishing societies are in North America, Europe is one tier below and Asia is far behind” (www.salon.com/2002/03/25/asians/?x).

Mahbubani's (2002) observation highlights the fact that the innovation performance of a society can change drastically over time. Take China as an example. Before the middle of the Ming Dynasty (1368–1644), China was a world champion in invention. However, since then, it has failed to maintain its global leadership in innovation. Although China's innovation performance has increased in the recent years, frame-breaking innovations are more likely to originate from European and North American countries than from China. This has been referred to as the Needham Puzzle, and many explanations have been offered for the phenomenon: (1) The Chinese

did not develop a scientific method rooted in analytical thinking (Nisbett, 2003); (2) there is a lack of educational diversity and ideational fluidity in China; and (3) China was not open to the outside world. In contrast, Western cultures encourage experimentation, tolerate failure, and accept deviance. Furthermore, in the West, there is strong institutional support for decentralization of and competition in R&D (Augier, Guo, & Rowen, 2016). There are other possible explanations: (1) China's defensive responses to external threats and fatal infectious diseases in the mid-1600s promoted conformity; (2) the shift of emphasis from rationalism to subjectivism in Confucianism discouraged scientific thinking; and (3) the propagation of moral particularism in China after the middle of the Ming Dynasty had directed Chinese intellectuals' attention from technology to ethics (Liou, Kwan, & Chiu, 2016).

Systematic historiometric research has been performed to identify the factors that influence historical variations in a society's creative performance (Simonton & Ting, 2010). The evidence from this research shows that in both Eastern and Western histories, during periods of political instability and conflicts, if there were highly creative individuals in the country who could inspire creative productions, creativity flourished. This was the case probably because political conflicts destabilized established structures, institutions, and norms, whereas the availability of champions inspired new ideas and attracted followers.

Nonetheless, societies differ in how much their creative outputs may benefit from political instability. Political instability had greater influence on creative performance in the West than in the East, because in the West, political fragmentation and civil disturbances often led to greater tolerance of ideational diversity. In contrast, in Eastern cultures, political fragmentation often bred a strong desire for political unification and ideological uniformity (Simonton & Ting, 2010). In addition, the spread of ideologies has had a stronger positive impact on creativity in the West than in the East, because Western ideologies privilege individualism, empiricism, self-expression, and scientific creativity, whereas those in the East (e.g., Confucianism) do not (Simonton & Ting, 2010).

CREATIVITY AND CULTURAL DIFFUSION

As we mentioned earlier, culture evolves through the process of progressive modifications and refinements of the initial ideas and practices (Donald, 1991). Typically, an individual receives inspiration from different sources and combines these inspirations creatively to invent a new idea (Gabora, 2018). These ideas then evoke inspiration in another person. People can get inspirations from other people and things in their own or other cultures.

Agent-based modeling results (Gabora, 2018) show that it is this process of inspiration and progressive refinement of ideas that keeps cultures alive. When social learning is restricted to imitation and faithful reproduction of existing ideas or practices, the culture will soon lose its fitness for survival, because it fails to generate new ideas and practices that are responsive to the changing environment. However, if social learning allows for ratcheting or progressive refinement of existing ideas and practices, the culture will be able to maintain and raise its fitness for survival. From this perspective, a creative idea is not just one that is novel and useful, it must also be inspiring and communicable.

However, culture constrains how communicable an idea is. Research shows that ideas that are *minimally* counterintuitive are more memorable and have a greater chance of being selected for reproduction in the culture (Kashima, 2014; Norenzayan, Atran, Faulkner, & Schaller, 2006). These ideas contain some elements that challenge and others that resonate with culturally shared beliefs or knowledge.

Take transmission of scientific knowledge as an example. It is reasonable to assume that how inspiring and communicable a scientific finding is depends primarily on its levels of novelty and usefulness. Indeed, in 1996, Sternberg and Gordeeva found that psychological scientists agreed that six factors would make an article in psychology impactful: theoretical significance, practical significance, substantive interest, methodological interest, value for future research, and quality of presentation. However, bibliometric analysis of scientific papers (Hao & Chiu, 2016) indicates that political culture and religion are major predictors of how likely scientists from a certain culture will cite the works of scientists in other cultures. For example, scientists in countries that joined the North Atlantic Treaty Organization (NATO) before the fall of the Berlin Wall are more likely to cite scientists who are in the same cluster of countries than those who are not. Likewise, scientists in countries that joined NATO after 1989 are more

inclined to cite scientists from (vs. outside) the same country cluster. Knowledge traveled along the Silk Roads in the past. Bibliometric studies showed that along the new “silk roads” between Asia and Europe, scientists from Muslim countries are more likely to cite scientists from other Muslim countries than from non-Muslim countries. Likewise, scientists from Buddhist or Christian countries are more likely to cite scientists from countries that practice the same (vs. a different) religion. To control for possible language effects, in these bibliometric studies, only English publications were included.

In summary, inspirations enable innovation and evolution of culture. At the same time, cultural factors constrain not only how likely creative ideas are generated but also how inspiring those ideas are seen to be and how far these ideas can travel across minds, particularly minds with different cultural mentalities. From this perspective, culture and creativity/innovation support and constrain each other.

CONCLUSIONS

In this chapter, we have reviewed the latest research on the reciprocal relationships between culture and creativity/innovation. We have examined cultural differences in creativity at both individual and societal levels; how cultural diversity impacts the creative/innovative performance of individuals, groups, and societies; factors that influence historical variations of creative performance in a society; and how culture constrains diffusion of new ideas and knowledge. Our review highlights the importance of differentiating cultural processes at individual, group, and societal levels, and the utility of understanding creativity/innovation as multifaceted, multistage processes.

More importantly, the existing research indicates that culture is a living system of ideas and practices (Morris, Chiu, & Liu, 2015). Through creativity and innovation, culture is constantly being refined and remade. However, as a knowledge tradition, culture also sets limits on how likely transformational versus incremental ideas are created, selected, and accepted by people in their own and other cultures, and what ideas tend to be seen as inspiring and communicable. Research on culture and

creativity/innovation also highlights the crucial role intercultural interactions play in the maintenance of cultural traditions (through resistance to cultural borrowing and mixing) and how these interactions enable cultural changes.

NOTE

1. West (2017) found that as the size of a city grows, the number of patents per capita increases superlinearly, and so do crime rate and disease prevalence. This finding raises the issue of whether unbounded growth of cities is sustainable.

CHAPTER 27

Social Class as Culture

Michael W. Kraus, Bennett Callaghan, and Peter Ondish

Social scientists have studied social class for centuries, but cultural psychologists have only recently joined this undertaking. In this chapter, we define social class and differentiate it from relevant rank-related constructs, as well as review the most recent theoretical and empirical trends in the psychological study of social class. Specifically, we touch on four emerging theoretical perspectives in the study of social class: the social-cognitive perspective, the scarcity perspective, the culture perspective, and the life-history strategies perspective. We leverage each of these theoretical traditions as a tool to help explain how social class influences social perception, relationship strategies, health, and cognitive functioning. Finally, we discuss several future directions in the study of social class and the promise that this construct has for understanding big societal questions related to the causes of health, educational, and economic inequalities.

Scholars across the social sciences have examined how external social environments powerfully influence who we are and how we behave (Lewin, 1951). This orientation is on full display in any study of culture, and in particular, in the social-psychological study of social classes (Adler et al., 1994; Kraus, Piff, Mendoza-Denton, Rheinschmidt, & Keltner, 2012; Stephens, Markus, & Fryberg, 2012). Few other social-contextual variables exert the kind of systematic influences on human experience and well-being across the life course as does social class—which shapes political participation, health, mortality, well-being, and behavior across countries and cohorts (e.g., Kraus et al., 2012). In this chapter, we take an extensive

look at the cultural psychology of social class, focusing in particular on the ways in which scholars and researchers from throughout the social sciences conceptualize its influence on our everyday lives. We have chosen to focus on the previous decade of research on the topic of social class, though we also ground this recent work in past theoretical and empirical traditions. As well, we focus specifically on recent research in the fields of social and personality psychology on the topic of social class.

We begin the chapter itself with the challenging task of operationalizing a construct as multifaceted and multidetermined as social class. From there, we review the recent theoretical traditions in the study of social class in psychological science. Importantly, throughout the review of these traditions, we take steps to directly point out the ways in which the theories lead to important points of convergence and divergence in the study of social class as it relates to psychological processes and mechanisms. Through an integrated discussion of social class theory, we seek to uncover novel insights and predictions about the ways in which social class shapes emotion, conceptions of the self, group processes, and relationships with others. Finally, we close the chapter with a consideration of social class within the unique cultural context of the countries and regions in which the individual is socialized (e.g., I. Grossmann & Huynh, 2013). We highlight in this final section the similarities in the ways social class influences psychological processes across cultures, as well as some initial findings that predict the way cultures shape social class.

THE ECONOMIC CONDITIONS OF OUR LIVES: DEFINING SOCIAL CLASS

Fundamental to any study of social class is a working definition of the construct. Though social scientists have studied social class for centuries, the psychological study of social class lags far behind its sister disciplines—much of the psychology research on social class has occurred during the last decade, and scholars still seek consensus on the definition of the construct (Kraus & Stephens, 2012; Liu et al., 2004). Here, we start with a broad working definition of social class, then describe the (many) ways in which researchers measure the construct.

Some suggest that social classes are superficial categories with negligible impact on everyday life, and that these differences are only trotted out strategically to divide Americans in political discourse (Kingston, 2000). In fact, when American study participants are asked about the extent to which social class categories are permeable, they tend to wildly exaggerate the ease with which people move fluidly up the economic hierarchy (Davidai & Gilovich, 2015; Kraus & Tan, 2015; Kraus, 2015; see [Figure 27.1](#)). In reality, individuals' daily lives are sorted largely in terms of social class: Actual class mobility is low in most countries, and particularly so in the United States (Burkhauser, Feng, Jenkins, & Larrimore, 2011). Consider, for example, that people tend to date and marry (Sweeney & Cancian, 2004), live in neighborhoods and attend schools (Lareau, 2003), and work with other individuals who share comparable incomes and educational histories (Argyle, 1994).

FIGURE 27.1. Estimates of social class mobility, collected from a sample of online participants, as compared to actual mobility statistics from the Current Population Survey. The chart shows that participants significantly overestimate the percentage of people in the bottom 20% of incomes who move to the top 20% (left panel) and attend 4-year colleges and universities (right panel). Data from Kraus and Tan (2015).

As social class has connections to many societal institutions, defining and measuring the construct with precision is a constant challenge for social and cultural psychologists. On the one hand, some contemporary definitions of social class are concerned primarily with the level of economic resources

that individuals possess (Mullainathan & Shafir, 2013). “Social class,” in resource terms, is the way in which levels of experienced resources change how individuals perceive their social environments and relationships (Kraus et al., 2012). Material accounts of social class tend to measure the construct in terms of the amount of objective resources that individuals possess—including their levels of income (or debt; Drentea, 2000), occupational status (Oakes & Rossi, 2003), or educational attainment (Snibbe & Markus, 2005). Empirical studies with large, representative samples ($N = 10,308$) find that these three indices of material resources tend to correlate highly, but not perfectly, which suggests that they are relatively distinct aspects of an individual’s social class ($r = .42$ for income and education; $r = .53$ for education and occupational grade; $r = .58$ for income and occupational grade; Singh-Manoux, Adler, & Marmot, 2003).

Researchers have argued recently that accounts of social class that rely exclusively on objective resource disparities are incomplete for two reasons: First, relative standing is an important feature of social hierarchies (Anderson, Kraus, Galinsky, & Keltner, 2012; Norton, 2013) and social class in particular (Kraus, Tan, & Tannenbaum, 2013); that is, a core component of social class is individuals’ local comparisons of their own class position to that of others (Adler, Epel, Castellazo, & Ickovics, 2000; Callan, Ellard, Shead, & Hodgins, 2008). Specifically, individuals experience their social class position within their small social groups, local community, and society at large by comparing their own material resources to those of others (for a review, see Kraus et al., 2013). This ranking process is facilitated by the accurate signaling of social class to others during brief social interactions (Kraus & Keltner, 2009), and by the tendency for individuals to share accurate information about the self in order to facilitate interactions (e.g., Ambady & Rosenthal, 1992). Thus, in addition to levels of material resources, the experience of social class involves the assessment of one’s position in the class hierarchy relative to others.

Local rank comparisons are a fundamental process in mammalian social life. In nonhuman primates, local position is well defined in display behavior, is negotiated in status contests, and has important interpersonal outcomes (de Waal, 1986). For example, even in stable hierarchies of nonhuman species, low-ranking individuals tend to show higher chronic levels of glucocorticoids, a hormone released in response to increasing

metabolic demands (Sapolsky, 2004; Sapolsky, Romero, & Munck, 2000). In contrast, high-ranking nonhumans typically experience greater social affiliation from others (e.g., Watts, 2010), along with increases in reproductive opportunities (Abbott, 1984; Wickings & Dixson, 1992).

Local position in the hierarchy is crucial for shaping life outcomes in the human social class hierarchy: Local differences in income influence happiness and well-being, with those high in income experiencing greater well-being than their lower-ranking counterparts (Boyce, Brown, & Moore, 2010; Boyce, Wood, Daly, & Sedikides, 2015). When examining perceptions of local social class position, a similar pattern emerges: Awareness of one's high-status position is associated with higher levels of self-rated and physiological health relative to those perceiving themselves at the bottom of the class hierarchy, and these associations persist even after accounting for objective resource measures of social class (Adler et al., 2000; S. Cohen et al., 2008).

Researchers have a number of tools at their disposal for measuring how individuals perceive their social class rank. The most widely used index of perceived social class is the MacArthur Scale of Subjective Socioeconomic Status. In this measure, participants place themselves on a ladder with 10 rungs representing society (Adler et al., 2000). The highest rung of the ladder refers to people at the top of the social class hierarchy—those with the most income, education, and most prestigious jobs. The bottom rung of the ladder refers to the bottom of the social class hierarchy—those with the least income, education, and the lowest prestige jobs or no job. Subjective socioeconomic status (SES) can be assessed in terms of one's social class rank within society as a whole, or one's local community (Adler et al., 2000; Goodman et al., 2001). Other measures of social class rank include self-reports of social class categories (e.g., upper middle class, lower class; Bernstein, 1971; Mahalingam, 2003), the objective comparison of one's own material resources to that of others in one's local community (Boyce et al., 2010), direct comparisons to real or imagined interaction partners (e.g., Kraus, Horberg, Goetz, & Keltner, 2011a), or assessments of feelings of relative abundance or deprivation compared to local others (e.g., Callan et al., 2008).

Second, an exclusively resource-focused account of social class fails to highlight the ways in which social class leads to shared social contexts and

group identities held by individuals. Specifically, low social class mobility creates social settings in which individuals who share similar levels of objective resources can cultivate shared norms, values, and expectations for how to be a person (Kohn & Schooler, 1969; Shweder, 1990). These shared cultural realities create specific repertoires of values and behavioral scripts that are a product of a person's social class (Bourdieu, 1979; I. Grossmann & Varnum, 2011; Kohn & Schooler, 1969; Markus & Kitayama, 2003; Stephens et al., 2012). For example, individuals from different class backgrounds are guided by different manners and rules of etiquette (Elias, 1978; Lamont, 1992; Lamont & Lareau, 1988), honor different customs and habits (Bourdieu, 1979, 1985), express different aesthetic preferences for art and music (Snibbe & Markus, 2005), use language in different ways (Bernstein, 1971), employ different parenting strategies (Kusserow, 2004; Lareau, 2003; Pearlin & Kohn, 1966), and eat different foods (Monsivais & Drewnowski, 2009).

Researchers who take a cultural perspective on social class seek to understand how social class cultural norms can lead to mismatches between a person's particular definition of his or her social self (e.g., as a hardworking, collectively oriented, person looking to fit in) and the surrounding social context (i.e., individuals are expected to be independently oriented and to stand out from others; Stephens et al., 2012). In this work, educational attainment is often used as a measure of social class—given that level of education provides access to many social institutions and settings that expose individuals to different cultural contexts (Kraus & Stephens, 2012).

In this definition of “social class,” we are left with an understanding of the construct as defined by one's (1) level of available material resources, (2) subjective perception of position in the resource hierarchy relative to comparison others, and (3) the cultural norms and values individuals from a similar background share with one another. This definition makes specific suggestions for measurement of the construct—using both subjective and objective material indicators of social class—and for theoretical predictions about the ways in which social class influences basic psychology. To this latter point, we focus much of the chapter. Before we discuss theory, it is important to define social class independent of other social identity and hierarchical variables.

CLASS, POWER, GENDER, AND RACE: EMPIRICAL DISTINCTIONS

Social class is one source of social rank that individuals experience in their daily lives, and in some cases it converges with other rank-related constructs studied in social psychology, such as power, status, race, and gender. For example, elevated social class provides an individual with opportunities for increased “power” (defined as control and influence over others’ rewards and punishments; Domhoff, 1998; Keltner, Gruenfeld, & Anderson, 2003) and “status” (defined as elevated prestige and respect in the eyes of others; Anderson, John, Keltner, & Kring, 2001). Social class also, not surprisingly, has some parallels with the social categories of gender and race, categories that shape one’s resources and rank in society, as well as how others perceive one’s social standing (e.g., Steele & Aronson, 1995).

Social class and power are likely to have similar interpersonal effects on psychological processes, because both power and social class lead individuals to experience elevated levels of personal control and autonomy in their everyday lives (Kraus & Mendes, 2014; Kraus, Piff, & Keltner, 2011b; Lachman & Weaver, 1998). Aside from this similarity though, social class and power differ in terms of their specificity to a given relationship. For instance, a gas station manager may have very little power during the workday, but after work, he or she may have a great deal of control or influence over relationships at home. Perceptions of one’s social class standing may vary from situation to situation (e.g., S. Johnson, Richeson, & Finkel, 2011), but in general, given that class rank is the experience of one’s position in society at large, the experiences associated with social class are relatively stable. Thus, unlike power, which ebbs and flows from situation to situation, social class is likely to have broader and situationally consistent influences on how individuals view society, politics, and social institutions (e.g., Kraus & Tan, 2015).

Social class also varies with sociometric status, or the respect individuals have within their face-to-face social groups (Anderson & Kilduff, 2009). Those of high social class may achieve elevated respect and admiration in face-to-face groups more than their lower-class counterparts (Anderson et al., 2012; Kraus et al., 2012). Nevertheless, important empirical distinctions arise between these two rank-related constructs as well. For example, being

wealthy or well-educated does not guarantee one respect or admiration—wealthy individuals are often viewed as low in interpersonal warmth across a number of person perception studies (e.g., Fiske, Cuddy, Glick, & Xu, 2002).

As well, unlike both power and status, social class has the characteristics of a group membership variable. People identify with a particular social class (Hout, 2008), and tend to share environments and relationships with those from a similar background. Thus, whereas power and status involve individual positions within a hierarchy, social class links a person to a group of other individuals who share a similar standing in society (Kraus & Stephens, 2012) and should exert influences on group relations and intergroup interactions that are similar to that of cross-race and cross-gender exchanges (Côté, Kraus, Piff, Beermann, & Keltner, 2014).

Despite these group similarities, it would be overly simplistic to suggest that social class works the same way on basic psychological processes as do race and gender. For example, social class distinctions are less institutionalized in American society. While the U.S. census categorizes individuals based on race and gender, it does not categorize people according to distinct social class categories (DiMaggio & Garip, 2011; Hout, 2008). Also, unlike ethnicity and gender—social categories with relatively clear physical signals (e.g., Knowles & Peng, 2005)—people do not readily showcase their bank statements, degrees, or occupational titles. Though some studies suggest that behaviors and cultural aesthetics signal social class (Bourdieu, 1979), these signals tend to be far less diagnostic than those of race and gender. For instance, in studies of class signaling, correlations between observer estimates of social class and participant social class are far lower (r 's = .20–.30) than what is typically expected for judgments of race and gender using similar stimuli (Kraus & Keltner, 2009).

It is also possible for social class to change over time, with continued experiences in a different social class context. For example, it is possible (though unlikely, based on large surveys of economic mobility) for a person born into a working-class family to, with increasing educational attainment, income, and occupation status, become more used to an environment of high resources and elevated position relative to others (Burkhauser, Schmeiser, & Schroeder, 2007). In contrast, a person's racial or gender identity is likely—with few exceptions—to remain stable throughout his or

her life. All told, social class appears to be distinct from other social categories that rank people in society relative to others.

Having outlined our working definition of “social class” and differentiating the construct from other social categories and states that rank people in society, we now turn to the dominant theoretical traditions in the study of social class. We review each of these traditions in the section that follows, as well as highlight important implications and future directions suggested by each theory.

EMPIRICAL TRADITIONS IN THE STUDY OF SOCIAL CLASS

Four primary traditions seem to describe most clearly and completely recent research trends in the study of social class. Here, we describe each of these four perspectives—social cognition, cultures and selves, scarcity, and life-history strategies—and the future empirical directions suggested uniquely by a study of social class following from each perspective. See [Table 27.1](#) for a summary of key methodological considerations and theoretical predictions for each perspective.

TABLE 27.1. Current Theoretical Traditions in the Study of Social Class, Their Unique Measurement Strategies, and Theoretical Predictions for Relatively Lower-Class Individuals

Theory	Definition	Measure(s) of social class	Theoretical predictions for lower-class individuals
Social cognition	Resource and rank disparities create contexts that elicit persistent patterns in social perception and relationship strategies.	<ul style="list-style-type: none"> • Material resources • Perceived rank in society 	↑ Threat vigilance ↓ Personal control ↓ Dispositional explanation
Culture	Socialization in nonoverlapping social class environments creates norms, values, and expectations for how to be a person.	<ul style="list-style-type: none"> • Neighborhood conditions • Education attained 	↑ Interdependent self ↓ Uniqueness
Scarcity	Having lower amounts of valued resources at any time point reduces certain types of rational economic decision making and executive functioning.	<ul style="list-style-type: none"> • Current/past economic conditions 	↓ Executive functioning ↓ Future focus
Life history	Early-life resource scarcity creates strategies to help individuals best navigate life challenges and pass on their genes.	<ul style="list-style-type: none"> • Early-life economic conditions 	↑ Early reproductive strategies ↓ Health and longevity

A Social-Cognitive Theory of Social Class

In this theoretical perspective on social class, features of the social class environment—primarily an individual’s level of material resources or perceived position relative to others—elicit a persistent pattern of thought, feeling, and behavior in individuals. This perspective has roots in decades-old research indicating that job complexity influenced people’s style of social perception and degree of self-direction (Kohn & Schooler, 1973). In general, the social-cognitive perspective argues that exposure to high levels of resources or perceived rank—because these conditions are protective from threats and create individual opportunities—elicits a greater internal focus on one’s own goals, rewards, and outcomes. In contrast, environments of scarce resources and subordinate position expose people to fewer opportunities and greater threats, and as such, elicit an external focus on

environmental forces that interfere with or facilitate the attainment of one's own goals and rewards (Kraus et al., 2012).

Researchers studying social class from a social-cognitive perspective observe that social class contexts elicit these patterns of psychology across a number of domains, including how people see the self, how they perceive the environment, and how they relate to others. The social-cognitive perspective defines social class on a continuum in which rising resources and rank are accompanied by increases in internal focus—the social-cognitive pattern associated with upper-class individuals. Importantly, social-cognitive patterns can emerge based on the chronic exposure to environments of high (or low) resources and perceived rank, or through temporary exposure to these features of the social environment—such as being asked to think about members of one's university class that are higher than the self in social class during an experiment (S. Johnson et al., 2011). This feature of the social-cognitive perspective is perhaps what makes it unique from the cultural perspective—in which the experience of social class can be temporarily induced in a laboratory interaction through manipulating the features of the social environment related to relative economic resources (e.g., Brown-Iannuzzi, Lundberg, Kay, & Payne, 2015; Callan et al., 2008) or perceived position in the class hierarchy (Emery & Le, 2014; Kraus & Mendes, 2014; S. Johnson et al., 2011).

The social-cognitive perspective suggests two ways in which social class shapes basic patterns of perceiving the social world and relating to others. In terms of social perception, the resource scarcity and lower perceived position of lower-class individuals lead to perceptions of the self as beset by more external environmental threats and fewer means of personal control to influence those threats. In contrast, individuals with higher levels of material resources and superior positions in society experience reduced exposure to threats and have more of the necessary personal control and agency to combat these threats effectively and achieve desired goals and outcomes (Kraus et al., 2012).

Several studies highlight the existence of these reliable patterns of social perception: A meta-analysis reveals that relatively lower-class individuals report feeling more “hostility” toward others—defined as negative attitudes and beliefs about others—relative to their upper-class counterparts (Gallo & Matthews, 2003). More recent evidence extends these threat perceptions to

physiology—with lower-class children exhibiting heightened sympathetic nervous system arousal relative to upper-class children, while viewing an ambiguous video showing a child of similar age being asked to stay after class (Chen & Matthews, 2003). As well, research on stereotype threat finds that relatively lower-social-class students perform more poorly on academic tests, relative to upper-class individuals, but only if those tests are framed as diagnostic of ability and, therefore, threatening in their potential to reinforce negative group stereotypes. By contrast, individuals of all class backgrounds perform equally well when tests are framed in nonthreatening, nondiagnostic terms (Croizet & Claire, 1998; cf. Spencer & Castano, 2007). In general, while lower-class individuals see their lives as more constrained by environmental threats and by the whims of others, upper-class individuals report experiencing higher levels of personal control and agency in their everyday lives (W. Johnson & Kruger, 2005, 2006; Kraus & Keltner, 2009), and show greater preference for cultural practices that highlight personal choice and agency (Snibbe & Markus, 2005).

These enhanced beliefs in personal control and agency may elicit broad patterns of dispositional explanation among upper-class individuals; that is, believing in one's own agency elicits corresponding assertions that others experience the world in similarly agentic ways. In contrast, relatively lower-class individuals attend to the external environment and the potential threats and opportunities arising there and, as such, might be more likely to favor the social context when explaining the behaviors of themselves and others (Kraus et al., 2012). Several studies reveal this pattern of responses: Relatively upper-class individuals explain economic inequality more in terms of internal dispositions related to hard work, money management skill, and talent in comparison to lower-class individuals, who favored the social context in their explanations (e.g., educational opportunities, political policy; Kluegel & Smith, 1986; Kraus & Keltner, 2009). Furthermore, the tendency for upper-class individuals to favor dispositional and relatively lower-class individuals to favor contextual explanations has been observed in emotion explanations (Kraus & Keltner, 2009), explanations of personal life events of the self and others (I. Grossmann & Varnum, 2011), and in explanations of the genetic or social determinants of group membership (Kraus & Keltner, 2013; Mahalingam, 1998).

Applying these observations to the interpersonal realm, the social-cognitive perspective also makes specific predictions about relationship strategies: Awareness of external threats means that relatively lower-class individuals are likely to be more perceptive of and attentive to their social relations, more reliant on these relations for achieving desired outcomes, and more attentive to the hardships that others might experience. In contrast, relatively upper-class individuals are likely to seek relationships characterized by independence and freedom of expression, and are likely to be less aware of others' experiences, thereby reducing reliance on interpersonal interactions (see Stephens, Markus, & Townsend, 2007; Piff, Kraus, Côté, Cheng, & Keltner, 2010).

If social class shapes the ways that individuals attend to and rely on others, one hypothesis asserts that lower-class individuals should exhibit higher rates of prosocial behavior relative to their upper-class counterparts. Data converge with this expectation: For example, lower-income individuals give a higher proportion of their income to charity relative to their high-income counterparts (Independent Sector, 2002; Internal Revenue Service, 2007–2010; Current Population Survey, 2009; cf. Korndörfer, Egloff, & Schmukle, 2015; Andreoni, Nikiforakis, & Stoop, 2017). Although these patterns may be the result of unaccounted-for third variables related to religious tithing or donation reporting, laboratory studies reveal a similar pattern: Specifically, lower-class individuals give slightly more ($[\beta\epsilon\alpha] = -.22$) of their allotted 10 points to an anonymous partner in a dictator game than did higher-class participants, even after researchers controlled for ethnic background, religiosity, and age (Piff et al., 2010).

These tendencies of heightened prosocial behavior may also be related to the heightened capacity of relatively lower-class individuals to attend to and show concern for the suffering of others. For instance, high school-educated university employees scored higher on a measure of “empathic accuracy”—the ability to accurately read the emotions expressed by others—relative to their college educated counterparts (Kraus, Côté, & Keltner, 2010). As well, when viewing a video showing children contending with treatment for cancer, relatively lower-class individuals self-reported greater concern for the suffering child and reduced heart rate (indicative of social orientation responses to others' suffering) relative to their upper-class counterparts (Stellar, Manzo, Kraus, & Keltner, 2012).

Social Class as Culture

In many ways, the cultural perspective on social class advances and clarifies the process by which social class impacts basic social cognition. Specifically, though both perspectives emphasize the experience of levels of resources and perceived rank in society, the cultural perspective in particular suggests that these economic conditions create socialization processes that lead to the adoption of class-specific cultural practices in which individuals engage persistently across their lives—which we and others define as norms, values, expectations, and models for how to be a person (Bourdieu, 1979; Fiske & Markus, 2012; Markus & Kitayama, 2003). The social-class-as-culture perspective arises from the expectation that people from different class backgrounds grow up in vastly different and nonoverlapping social environments, with unique cultural practices and expectations that broadly shape who they are and how they behave (Kusserow, 2004; Snibbe & Markus, 2005; Stephens et al., 2012; Weininger & Lareau, 2009). Given the importance of unique social environments for the socialization of class-specific cultural practices, researchers who study social class as culture typically rely on measures of social class that best estimate the way in which social class environments are separated—that is, by levels of educational attainment (Kraus & Stephens, 2012; Stephens et al., 2012) or neighborhood wealth, given that individuals live in neighborhoods sorted in terms of social class (Haidt, Koller, & Dias, 1993; Sweeney & Cancian, 2004). As well, because cultural environments require years of socialization and accumulated cultural knowledge, temporary and laboratory-induced manipulations of perceptions of social class are relied on less in this theoretical perspective.

A cultural approach to social class suggests that distinct cultural environments of relatively lower- and upper-class individuals engender different models of the social self. For relatively lower-class individuals—referred to as “working class” in the cultural approach—the self is defined as fundamentally connected with others. Thus, when working-class individuals respond to their social environments, they do so while considering not only their own wishes and motives but also those of important others (e.g., friends, family members). In contrast, relatively upper-class individuals—referred to as “middle class”—tend to define the self as separate from others.

Thus, when middle-class individuals respond to their social environments, they do so by standing out and being unique (Stephens et al., 2012).

Several lines of evidence align with this theoretical perspective. Sociological research on early childhood environments supports the assertion that working-class and middle-class contexts socialize children using distinct models of the self. For example, working-class environments foster a “hard individualism” that stresses how important it is for children to follow the rules and maintain strong social bonds, whereas middle-class environments foster a “softer individualism” that allows individuals to explore their unique traits and abilities (Kusserow, 2004; Lareau, 2003). Structured interviews of working-class and middle-class parents suggests that middle-class parents are more likely to encourage their children to speak up, stand out, and have an opinion in school relative to their working-class counterparts (Weininger & Lareau, 2009). Other research indicates that middle-class individuals are more likely to establish friends willingly and align themselves with social groups of their own choosing based on personal preferences or interests (Reay, Ball, David, & Davies, 2001); are encouraged, even at a young age, to choose their own foods, books, and recreational activities (P. Miller, Cho, & Bracey, 2005); and are more likely to have extended social networks (Bowman, Kitayama, & Nisbett, 2009) relative to their working-class counterparts.

Research on choice nicely demonstrates the ways in which social class shapes cultural definitions of the self. When making choices, working-class individuals tend to feel more positive about making the same choice as a friend, whereas middle-class individuals tend to feel that a friend is copying their choices (Stephens et al., 2012). Middle-class individuals also feel a greater need to rationalize their choices. In one study, middle-class participants tended to show the spreading of alternatives effect—by valuing chosen over equally valuable items—whereas choices did not influence working-class individuals’ valuations (Snibbe & Markus, 2005). In another study, Stephens et al. (2007) approached college students and asked them to choose their preference of available pens, ostensibly for a marketing study. Students were presented with five options, four of which were identical pens, and one of which was unique. Students from working-class backgrounds were more likely to choose one of the four related pens, whereas those from middle-class backgrounds were more likely to choose the unique pen.

Together these studies provide evidence suggesting that individuals from middle-class backgrounds are more likely to use unique choices as expressions of their own unique self-concept.

A cultural perspective on social class also asserts that distinct environments and unique cultural models of the self should, over time and with some amount of social experience (though the precise amount is of some debate; see Dobbins, Schnyer, Verfaelie, & Schacter, 2004), engender distinct neuroanatomical and functional aspects of the brain (Han et al., 2013). Thus, any cultural differences between middle-class and working-class individuals should be recognized in patterns of brain activity—and a growing body of research supports this assertion. In one study, working-class and middle-class participants were shown faces, along with behaviors implying a trait (e.g., “She challenged a salesperson on every point the salesperson tried to make”). Later, the same face was presented, along with a trait that would describe the behavior (e.g., “argumentative”) or the trait’s antonym (e.g., “agreeable”). Despite participants from each group showing equal levels of memory for the behaviors, only the higher social class participants showed an N400 response—indicative of expectancy violation—when the faces were paired with antonyms (Varnum, Na, Murata, & Kitayama, 2012). These results indicate that the tendency to make spontaneous dispositional inferences when learning about a behavior was greater among middle-class participants than among working-class participants—and the effect was measureable at the neuronal level (Kitayama, Varnum, & Salvador, [Chapter 3](#), this volume; Varnum et al., 2012). We return to the burgeoning neuroscience of social class later in this chapter when considering future directions.

Social Class and Resource Scarcity

An emerging theoretical perspective in the study of social class is the idea that resource scarcities—such as low levels of income or material wealth—create consistent styles of social processing errors in individuals (Mullainathan & Shafir, 2014). The theory rests on the basic assumption that all human beings exhibit persistent deviations from rational economic forms of social cognition, and that under conditions of scarce resources, these

deviations become predictable: Specifically, when individuals are faced with scarce resources, (1) they make economic decisions that are driven more by present concerns and needs than by future ones, and (2) their efforts to plan, organize, and manage their behavior are disrupted (Mullainathan & Shafir, 2014). In essence, as resources become scarce, people cannot afford to pay attention to future concerns or plan for future behavior, because present concerns and threats loom sufficiently large (Mani, Mullainathan, Shafir, & Zhao, 2013; Shah, Mullainathan, & Shafir, 2012).

In a series of studies, Shah et al. (2012) tested this proposition directly by manipulating scarcity within a laboratory environment. For example, participants played a game in which they had a limited amount of time to respond to questions, or one in which they had to shoot a projectile into a target. The experimenters manipulated scarcity by varying either the amount of time participants had to respond to each question or the number of shots they had, respectively. When not under conditions of scarcity, participants planned their game responses with the future in mind—for instance, by not using their turns allotted for future rounds in the game earlier, when given this opportunity. In contrast, those under scarcity were much more likely to withdraw turns from their future allotment to deal with current game demands (Shah et al., 2012).

In similar work, Mani et al. (2013) presented shoppers at a New Jersey mall with vignettes designed to evoke financial concerns that were either relatively small or substantial. For example, they were told that they would have to spend either \$150 or \$1,500 on an emergency car repair. Following the experimental manipulation, participants filled out measures of cognitive performance (designed to measure problem-solving ability) and cognitive control (designed to measure the extent to which people can suppress automatic actions in favor of intentional ones). While scores for lower-class and upper-class participants were relatively similar in the smaller financial concern condition, higher-class participants outperformed lower-class participants in the substantial economic concern condition. Thus, the lower-income participants were not, in general, less cognitively apt than their upper-income counterparts, but they exhibited more errors when they were preoccupied with weighty financial concerns (Mani et al., 2013).

Natural fluctuations in resource scarcity reveal a similar pattern: Mani et al. (2013) administered cognitive performance tasks to a sample of Indian

farmers both immediately before the harvest (i.e., when scarcity was high) and after the harvest season (i.e., when resources were at their annual high). As predicted by the scarcity model, participants scored higher on cognitive tasks after the harvest than they did before the harvest. Importantly, this effect held no matter what time of year the participants reaped their harvest, as harvest cycles (and, subsequently, pretest and posttest timing) were staggered across participants (Mani et al., 2013).

While the more contemporary version of scarcity theory focuses on experimental designs that vary current economic conditions, research in neuroscience finds a similar pattern when examining the conditions of economic development: Specifically, those with lower economic resources tend to show greater deficits in cognitive performance than their counterparts with higher resources, particularly in the realm of executive functioning (Hackman & Farah, 2009; Lawson & Farah, 2017). Moreover, these deficits in executive functioning emerge early on in cognitive development (i.e., in the preteenage years; Kishiyama, Boyce, Jimenez, Perry, & Knight, 2009). Together, these findings highlight the important role that social class plays in shaping the cognitive functioning of individuals.

Social Class and Life-History Strategies

While the prior theories suggest that both one's current and past economic conditions influence the psychological experience of social class, the life-history strategies perspective suggests that early life represents a critical period for developing consistent patterns of social responses—and it is particularly during this time period that social class exerts the most influence on contemporary psychology (Griskevicius, Delton, Robertson, & Tybur, 2011a). According to life-history strategies theory, early-life environments are likely to influence the strategies that individuals use to navigate their social surroundings across the life course (Belsky, 1997; Kenrick & Luce, 2000). A life-history strategies perspective on social class is meant to answer a fundamental biological question: How can an organism best allocate its relatively scarce or abundant resources to increase its chances of survival and reproduction? The relative urgency surrounding one's reproductive agenda may be thought of on a “fast” to “slow”

continuum. Those on a slower course emphasize a slower pace of reproduction and typically delay having children and allocate more resources toward a fewer number of offspring. Those on a faster course emphasize a faster pace of reproduction and typically have children earlier and allocate resources toward the production of more offspring (Belsky, 1997; Ellis, Figueredo, Brumbach, & Schlomer, 2009).

Despite its broad origins in animal behavior, evolutionary biology, and ecology, a life-history strategies perspective also provides important insight into the study of social class. Specifically, resource availability might influence the particular strategy one adopts to combat one's environment; that is, if resources are abundant, then long-term life investments are more justifiable and may be a more normatively employed tool in an individual's survival repertoire—taking greater care and planning in mate selection would ensure the selection of the most desirable mates, who would provide the most optimal conditions for reproduction and survival. In contrast, if resources are scarce, then engaging in extra planning is less optimal, because scarcity suggests that too much planning might lead the individual to miss out on finite mating opportunities—due to death or other harm caused by resource scarcity. In this circumstance, more short-term mating strategies are likely to be the most optimal. These strategies, the researchers contend, are likely to be elicited when individuals are reminded of environmental threats (Griskevicius et al., 2011a).

Thus, a life-history strategies perspective suggests that individuals from lower social class backgrounds in childhood are more likely to focus on behaviors that favor present circumstances (e.g., having children early, taking immediate rewards) and discount the future, especially when reminded of environmental threats. Griskevicius and colleagues (2011a) tested this hypothesis across several studies by increasing the perceived local mortality dangers (environmental harshness) of participants' environments. Participants in one study read either an article about the many potential life-threatening dangers associated with living in the 21st century or a control article that was without any hints of personal mortality. Repeating this design across several studies, they found that in the mortality prime condition, participants with higher social class environments during childhood reported more negative attitudes about having children soon than did lower-class participants. Similarly, when primed with mortality,

individuals with lower social class during childhood reported a desire to have children sooner (6.7 years), whereas participants with higher social class during childhood reported wanting to delay having children further (9.3 years; Griskevicius et al., 2011a; cf. Griskevicius, Tybur, Delton, & Robertson, 2011b).

Together, these experiments suggest that lower social class environments in childhood elicit patterns of behavior that prioritize current circumstances over future outcomes. Importantly, across the studies, childhood social class environments predicted the kinds of life-history strategies participants followed, whereas current circumstances did not (Griskevicius et al., 2011a, 2011b). The relative predictive power of childhood over current social class suggests that these life-history strategies are put in place by early life conditions and systematically alter the life course of individuals across time.

One implication of life-history strategies research is that early-life social class environments might set people on health and well-being trajectories that influence their morbidity and mortality. Meta-analyses reveal that people with lower social class backgrounds tend to have higher rates of all-cause mortality in the United States (Adler et al., 1994) and the United Kingdom (Marmot & Shipley, 1996), and suggest a significant contribution of early-life social class environments. Several recent studies in health and epidemiology anticipate this pattern: In one of the first longitudinal studies testing this phenomenon, Chen, Cohen, and Miller (2010) brought children, ages 9–18, into the laboratory and measured their childhood social class and levels of salivary glucocorticoids (cortisol)—a stress hormone that indexes responses to threats that individuals contend with in their social environments (Dickerson & Kemeny, 2004)—over the course of 2 years in 6-month increments. Lower social class children showed larger increases in daily cortisol across time compared to those from higher social class environments. This longitudinal investigation shows the influence of early-life social class on health outcomes 2 years downstream.

In a similar study, G. Miller and Chen (2010) suggest that the effects of early-life stressors persist into adulthood. The researchers identified young adult women (ages 15–19) as either growing up in nonharsh or harsh environments, using questions such as “How often did a parent or other adult in the household swear at you, insult you, put you down, or act in a way that made you feel threatened?” Participants were brought into the

laboratory in another longitudinal study over four occasions, measured for episodic stressors that had occurred over the past 6 months, and provided tissue swabs to assess levels of pro-inflammatory phenotype. The young women coming from relatively harsh backgrounds showed, first, higher overall rates of pro-inflammatory phenotype than those from less harsh environments and, second, greater pro-inflammatory phenotype in response to a major life stressor occurring within the past 6 months (G. Miller & Chen, 2010). The results indicate that those from harsher early-life backgrounds tend to experience a chronically exaggerated pro-inflammatory response—which, over time, can reduce the immune system’s effectiveness in fighting disease or illness.

One recent advance in health psychology suggests a compelling mechanism for why early-life environments might be important for eliciting later life health outcomes. The research indicates a critical period in early life in which genes related to inflammatory responses become more or less likely to be expressed (Cole, 2012). Theoretical accounts of epigenetics suggest that early life environments set up genes to express phenotypes that are best adapted to deal with these acute harsh circumstances (e.g., elicit a larger inflammatory response in individuals who experience early-life physical trauma; Roberts & Jackson, 2008). If experienced over critical periods in development, such epigenetic changes in the expression of genes have the potential to “lock in” this particular phenotype across the life course. Such epigenetic changes can lead early life environments to exert a larger influence on health trajectories—in that these early environments program the body to express certain health profiles or suppress others. Tests of the epigenetic hypotheses related to social class are relatively rare, but initial evidence is suggestive: In one study demonstrating this phenomenon, Chen and Miller (2012) found that early-life lower social class individuals had higher epigenetic indicators for genes related to pro-inflammatory processes (e.g., natural killer cells, interleukin-6) than their early-life higher social class counterparts. This work represents a promising advance for understanding the precise mechanisms that allow early-life social class to predict later life health and behavior.

SOCIAL CLASS THEORIES: AN INTEGRATION

Each of the four theoretical perspectives we have reviewed thus far offer important insights into conceptualizing and studying social class from a psychological perspective. As research in cultural psychology matures, integrating these perspectives becomes an important undertaking. In this section, we attempt to integrate the social-cognitive, culture, scarcity, and life-histories perspectives in terms of their behavioral implications, cognitive functioning, and implications for health and well-being.

Social Interdependence as a Class-Based Behavioral and Survival Strategy

Research on social class seems to converge on the notion that relatively lower-class individuals are more interdependent with their social environments and those in their immediate social context (Kraus et al., 2012), but theories diverge about the origins of these differences in behavior: For the social-cognitive perspective, environments of scarce resources and subordinate rank create greater social interdependence out of necessity. People of lower social class turn to others in order to find a way to work through harsher and more threatening social environments, and this response pattern need not—though it could—require socialization processes. This is similar to the logic of the life-history strategies perspective, although in that perspective, early-life social class environments set in stone a pattern of relationship-seeking specifically for early reproduction purposes (Griskevicius et al., 2011a). In contrast, the cultural-psychological perspective clarifies the process of eliciting greater social interdependence among lower-class individuals—by learning models for how to be a person that are passed on by parents and other adults (Stephens et al., 2012).

That three (social-cognitive, cultural, and life-history) of our four reviewed social class theories converge on these behavioral patterns is indicative of remarkable convergence in research on social class, and suggests some avenues for future inquiry. For instance, greater reliance on interdependence and social connection with others might mean that relatively lower-class individuals will prefer and excel in environments in which such norms of interdependence and social connection are shared,

valued, and expressed. Recently, researchers applied this insight to investigate the impact of an inclusive college environment on the academic outcomes of first-generation college students. The researchers recruited a sample of first-year, first-generation students and exposed half to a panel of senior students who discussed the unique challenges that first-generation students experience, based on their social interdependence at the university. These students were then followed for their entire first year at the university, and their grade point averages (GPAs) were measured throughout. First-generation college students performed worse on academic measures than did continuing generation students (i.e., students whose parents went to a 4-year university as well), except when they were exposed to senior students discussing the challenges of being interdependent at a university (Stephens, Hamedani, & Destin, 2014).

Lower-class individuals face more health and mortality deficits than do their upper-class counterparts (Adler et al., 1994), but recent research suggests that beliefs that one's outcomes are collaborative—that is, influenced by one's relationships with others—may improve the health and well-being of lower-class individuals and reduce this health gradient. In essence, beliefs that social groups and individuals are characterized by heightened social connections based on external environmental influences might enhance the well-being of lower-class individuals, since these perceptions are consistent with the way that lower-class individuals have experience solving problems. In contrast, individuals from upper-class backgrounds might prefer to contend with social threats that are under individual control and influence.

There is preliminary support for this prediction: For instance, in a series of studies examining well-being among samples of friends and romantic partners, relatively lower-class individuals, assessed in terms of subjective and objective indicators of social class, felt higher rates of subjective well-being when they belonged to highly committed close relationships. In contrast, relatively upper-class individuals' relationship commitment did not predict the subjective well-being of these individuals in friendships or close relationships (Tan et al., 2018). In other research, perceptions of social groups as socially constructed—specifically, exposure to information suggesting that position in society is caused by external environmental forces rather than by genes—predicted elevated self-rated health for

relatively lower-class individuals but not upper-class individuals (Tan & Kraus, 2015; see [Figure 27.2](#)).

FIGURE 27.2. The relationship between social class and self-rated health (“My health is generally good”) as a function of exposure to a science article suggesting that a person’s position in society is genetically based (Genetic) or not genetic (Nongenetic). Data from Tan and Kraus (2015).

A focus on social interdependence might also influence the decision-making strategies of individuals from relatively lower-class environments. Specifically, persuasive messages that focus on the ways in which social connection and interdependence are valued, promoted, or fostered by a particular product or individual, may influence the decisions of relatively lower-class individuals—who favor these social values—more than the decisions of their upper-class counterparts. Recent examination of this potential phenomenon has focused on politics. In some initial research, university students were told about the importance of voting in university elections—in which average participation rates are roughly 12% for the entire student body (Campus Student Election Commission, 2018).

These messages were framed, based on either competence (i.e., voting ensures a more effective student government) or interdependence (i.e., voting ensures a warmer student government that connects with its constituents and shares its concerns). Afterwards, participants reported their intentions to vote in an upcoming student election. In the study, students from lower subjective social class backgrounds intended to vote less, a finding consistent with general election trends in the United States

(Krosnick, 1991). However, the message also mattered: University students from relatively lower-class backgrounds indicated a lower likelihood of voting in upcoming student elections following the competence framing, but they indicated intentions similar to those of upper-class students following interdependence framing (see [Figure 27.3](#); Callaghan, Kraus, & Dovidio, 2018).

FIGURE 27.3. The relationship between subjective social class and intentions to vote in student elections as a function of competence and interdependence framing at one standard deviation above and below the mean. Error bars represent standard errors of the mean. Data from Callaghan, Kraus, and Dovidio (2018).

Social Class, Cognition, and Neuroscience

Many scholastic aptitude tests, college entrance exams, and job assessments rely on standardized testing that in part indexes general intelligence and is moderately correlated with indices of social class (Gottfredson, 2004; Nisbett, [Chapter 7](#), this volume; Stephens et al., 2012). Several theoretical perspectives on the psychology of social class provide important suggestions with respect to how to interpret correlations between intelligence assessments and social class. For instance, the cultural perspective indicates that class differences in intelligence assessments include differences in both

mental ability and implicit cultural knowledge, the latter of which leads individuals from higher social class environments to score systematically higher—as a result of their shared cultural experiences with creators of the test content—relative to their lower-class counterparts (Stephens et al., 2012).

The life-history strategies perspective suggests that assessments of cognitive ability covary with social class, based on the content of early-life environments. These early environments may moderate the expression of heritable traits—with these genetic patterns unfolding in differences in mental ability that emerge early in life and maintain throughout development. In particular, evidence from twin studies points toward this possibility: Twins reared from lower social class family environments show lower heritability of intelligence and mental ability than did twins reared in higher social class family environments (Turkheimer, Haley, Waldron, d’Onofrio, & Gottesman, 2003), and these differences emerge in mental ability in the first few years of development (Tucker-Drob, Rhemtulla, Harden, Turkheimer, & Fask, 2011). This finding is consistent with the notion that early-life environments are crucial in establishing patterns that carry across the lifespan. Early-life environments, for example, might moderate the degree to which genotypes are expressed phenotypically (e.g., Nisbett, 2008; [Chapter 7](#), this volume). Relatively higher-class children, across the board, are likely to have access to the types of resources needed to cultivate inherited intellectual abilities, whereas lower-class children might not necessarily have such access. Thus, even “naturally” intelligent children raised in challenging circumstances may perform worse than might be expected based on their genotype. (These are behavioral genetics studies—so precise genes and mechanisms remain unknown).

In contrast to these perspectives, the scarcity approach suggests that class differences in cognitive ability are also a function of *current* resource circumstances; that is, the same individual would score lower in intelligence or cognitive aptitude on a test when resources were scarce than when resources were abundant. Evidence for this pattern is observed in the aforementioned studies, wherein farm workers scored worse on mental ability assessments before the harvest, when resources were scarce, relative to after the harvest, when resources were abundant (Shah et al., 2012). Other work indicates that *social* resource scarcity might also impede cognitive

function. For instance, research on stereotype threat in the realm of social class indicates that the social threat of having the burden of debunking stereotypes about the intelligence of one's social class group impairs cognitive function (Croizet & Claire, 1998; Spencer & Castano, 2007; cf. S. Johnson et al., 2011).

The field of neuroscience has provided a number of new tools (functional magnetic resonance imaging [fMRI], electroencephalography [EEG], and event-related potentials [ERPs]) that have the potential to uncover the precise processes and mechanisms for relationships between cognitive ability and social class. Several theories in cultural neuroscience contend that different social contexts lead to different functional neural organization (e.g., Kitayama & Uskul, 2011) and this is certainly true of social class. In the realm of cognitive deficits, review articles conclude persistent deficits in cognitive abilities for lower-class individuals relative to upper-class individuals in the realm of executive functioning (Hackman & Farah, 2009; Kishiyama et al., 2009).

Recent insights in neuroscience also suggest social class differences in processing style when considering others in the social environment. As noted, some research suggests that relatively higher-class individuals are more likely than their lower-class counterparts to make spontaneous dispositional attributions that produce expectancy violations (indexed by an N400 response) when incongruent information about a target is later presented. Evidence for greater social interdependence among lower-class individuals relative to their upper-class counterparts has also received convergent evidence in the realm of neuroscience. In recent fMRI studies by Muscatell and colleagues (2012), the researchers examined brain activation while viewing social stimuli. In this work, researchers examined differences in mentalizing while viewing pictures of others by examining activation in the dorsal medial prefrontal cortex and the medial prefrontal cortex—regions associated with considering others' mental states. The researchers observed greater activation in these regions while viewing pictures of others for lower, in comparison to higher, social class individuals (Muscatell et al., 2012). In a similar vein, a recent ERP study found greater activation in the front-central PS response—a response associated with empathic concern—to images of others in pain among lower-class individuals relative to upper-class individuals (Varnum, Blais, Hampton, & Brewer, 2015).

These initial insights from neuroscience are an encouraging avenue of future research on the cultural psychology of social class. Using neuroscience paradigms might clarify relationships between measures of cognitive functioning and social class by determining where in the cognitive process these differences emerge, and might provide insights into how differences in social perception develop at the neuronal level (e.g., Kitayama & Uskul, 2011; Varnum & Kitayama, 2017). As well, research in neuroscience might uncover insights about the development of neuronal differences in brain development and cognitive functioning; for example, are the neurological consequences of social class indelibly set early in life or do current circumstances amplify or attenuate such cognitive effects?

Social Class, Health, and Well-Being

Each theoretical perspective on social class has implications for the ways in which lower social class relates to patterns of health and well-being, and to ways in which negative health trajectories can be reduced for lower-class individuals. Once again, the theoretical perspectives perhaps differ most in the proposed relative influence of current and past circumstances on health and well-being.

In both the social-cognitive and scarcity accounts, current lower levels of resources or reduced rank relative to others elicit patterns of social judgment and behavior that theoretically cause stress and reduce well-being (Adler et al., 1994, 2000). The social-cognitive perspective relates directly to theoretical work on social comparison (Tajfel & Turner, 1979) and economic inequality (Wilkinson & Pickett, 2006), which suggest that the constant comparison of one's subordinate social position relative to others creates competition, dissatisfaction with present circumstances, and belief in a lack of societal fairness (Kraus et al., 2013). Over time, these sorts of beliefs elicit feelings of reduced personal control and influence over one's life, and potentially, reduced health and well-being (W. Johnson & Krueger, 2005; Lachman & Weaver, 1998).

According to the scarcity account, financial decisions conducted under conditions of scarcity have the unintended consequences of mortgaging future needs, such as seemingly far-off or unlikely health emergencies, in the

service of solving immediate needs. These short-term strategies, over time, may create a self-perpetuating process that reduces an individual's ability to make sound long-term health decisions, such as investing in adequate health insurance or taking advantage of health-related initiatives (Mullainathan & Shafir, 2013). According to these perspectives, changing one's relative position or the course of one's financial and investment patterns may potentially improve health outcomes.

In contrast, both the culture and life-history strategies accounts of social class suggest that past circumstances set in motion norms, values, expectations, and behavioral strategies that elicit persistent health disparities across the life course. The precise mechanisms for the influence of past circumstances on health and well-being are manifold and not yet empirically well supported. The culture account might suggest that learned behaviors, such as eating less nutritious foods, would elicit poor health among lower-class individuals (Darmon & Drewnowski, 2008). However, it is difficult to disentangle the learned behavior of eating unhealthy foods from the low availability and prohibitive cost of healthier foods in lower-class neighborhoods (Darmon & Drewnowski, 2008). Other work suggests that relatively lower-class individuals face social threats as a result of their cultural backgrounds—expressions of individuals' lower-class identity can lead others to perceive them as unsuited for a particular social context, such as at college or in middle-class workplaces. Thus, relatively lower-class individual's expressions of the self are marginalized and devalued in social contexts in which they are the minority—thereby eliciting poor long-term health (e.g., Markus & Hamedani, [Chapter 1](#), this volume; Markus & Kitayama, 2003; Stephens et al., 2014).

The life-history strategy perspective contends that individuals learn risky life strategies when exposed to harsh early-life environments. These strategies elicit behaviors, such as early sexual activity, lower delay of gratification, and reward seeking, that expose individuals to greater health risks at earlier ages (Griskevicius et al., 2011a). Such strategies may also be supported, as we mentioned previously, by gene expression: Harsh early-life environments increase the expression of genes for pro-inflammatory processes—suggesting that early-life social class sets in motion a pattern of immune responses that increases morbidity and mortality across one's life (G. Miller & Chen, 2010).

How behavioral or cultural strategies elicit long-term health consequences for lower-class individuals and how these strategies relate to gene expression remain important and understudied aspects of social class research in psychological science. Clearly, however, lower social class is reliably associated with poor health in the United States (Adler et al., 1994), and even in countries such as the United Kingdom, where health care is provided to all citizens (Marmot et al., 1991). Longitudinal research in particular, which may help assess the mechanisms and trajectories of poor health as they relate to social class, might reveal new insights about intervention strategies. The relationships between past and current economic circumstances and health are particularly deserving of additional scrutiny, as the ability to improve health by improving economic conditions offers some clear directions for health intervention strategies—primarily involving the reduction of poverty in societies (Wilkinson & Pickett, 2006).

THE FUTURE OF SOCIAL CLASS RESEARCH

In the final section of this chapter, we highlight what we think are four important, emerging research directions in the psychological study of social class: ascending the class hierarchy, crossing social class boundaries, reducing economic inequality, and understanding social class across and within cultures. Where relevant, we have also outlined preliminary attempts to study these phenomena empirically.

Ascending the Class Hierarchy

Because social class is a consistent predictor of health (Adler et al., 1994) and subjective well-being (Howell & Howell, 2008), many people from relatively lower social class backgrounds desire to move up the economic ladder. Such beliefs are also inherent to the “American Dream” of equality of opportunity and a frequent striving of people coming to the United States from other countries and cultures. In practice, though, ascending the social class hierarchy is fraught with important challenges and unforeseen obstacles. Researchers in the social sciences have begun the process of

attempting to understand how individuals can navigate these obstacles and ascend the class hierarchy.

Research suggests several formidable barriers to ascending the class hierarchy. First and foremost, financial constraints place caps on the amount that individuals can invest in educational opportunities, future economic success, healthy food choices, and sound long-term financial decisions (Cohen, [Chapter 6](#), this volume; Mullainathan & Shafir, 2013), all of which may combine to constrain the hierarchical advancement of individuals at the bottom of the class hierarchy and require additional talent, effort, and luck to advance.

On top of these financial constraints, relatively lower-class individuals can feel a lack of fit between their own cultural identity and the values of social institutions, such as higher education, that are key to advancement. For instance, when asked to think of how high-achieving their university was, middle-class Northwestern University students performed more poorly on executive functioning assessments—a cognitive ability that is essential to success in college—than did their more wealthy counterparts (S. Johnson et al., 2011).

In parallel evidence on belonging, university students from differing class backgrounds were asked about their preferences for a list of jobs varying from working-class occupations (e.g., carpenter, firefighter) to middle-class occupations (e.g., research scientist, accountant). Despite the fact they were currently enrolled at a university, and, presumably, preparing for middle-class jobs in the future, relatively lower-class university students, measured in terms of identified social class category, showed no preference for middle-class jobs over the working-class ones. In contrast, relatively upper-class students discriminated highly between the two, strongly preferring middle-class occupations. These results indicate that working-class students may identify more strongly with aspects of their working-class background, and these positive aspects of identity may inadvertently serve as barriers to academic achievement and occupational success (Ondish & Kraus, 2018; see [Figure 27.4](#)).

FIGURE 27.4. Preferences for working-class and middle-class occupations as a function of self-reported social class category. Error bars represent standard errors around the mean. Data from Ondish and Kraus (2018).

In this study’s follow-up research, only when these relatively lower-class individuals were threatened by a manipulation that called their social group “lower class” versus “working class” did the students become more likely to prefer the middle-class occupations (Ondish & Kraus, 2018). These preliminary results suggest that people may see potential conflicts among maintaining a genuine positive social identity, cultivating feelings of belonging, and attempting to ascend the class hierarchy.

Notwithstanding these social and resource challenges, some evidence provides promise for interventions to improve class mobility. In terms of navigating financial uncertainty, a large-scale six-country poverty intervention—aimed exclusively at helping individuals to manage their own finances in preparation for the future (e.g., providing a savings account, advice on money management, home visits, health education, and technical skills training)—significantly improved food security, savings, and mental and physical health across the six countries (Banerjee et al., 2015).

Another intervention strategy has been used recently to affirm the goals of relatively lower-class college students attempting to ascend the class hierarchy. Half of 700 biology students were exposed to an intervention aimed at affirming the values these students have—in essence making them believe that their biology-related goals could become a reality. This

intervention reduced the achievement gap between first-generation students and ones whose parents attended college by 50%. The intervention also increased first-generation students' continuing to the next biology class in the series and significantly improved overall grade point average (Harackiewicz et al., 2014; cf. Stephens, Townsend, Hamedani, Destin, & Manzo, 2015).

This research suggests that psychological interventions can be effective in promoting class hierarchy ascendance for those attempting to move outside of poverty through higher education. Future research would benefit from a focus on optimizing interventions at various stages of the life course. What types of early educational and psychological interventions (e.g., Head Start), for example, might have lasting effects on social class mobility for lower-class individuals? Given the influence of early life experiences on social class psychological processes, early interventions might prove particularly fruitful for improving class mobility.

Crossing Class Boundaries

Often scholars think of social class without considering the group-based processes involved in one's class identity. This is likely because social class is low in visibility in society relative to other social categories—as noted earlier, people rarely display their occupation titles and bank statements to be viewed by others, and active discussions of the absence of social classes occur in some highly unequal countries like the United States (Kraus & Stephens, 2012). Moreover, much of society is sorted in terms of social class; people engage in relationships, go to school, live in neighborhoods, and work with individuals from similar backgrounds, which make cross-class contact unlikely (Lareau, 2003; Sweeney & Cancian, 2004). Thus, crossing class boundaries and identifying interclass interactions is something with which people have less experience. Despite the lack of salience of social class disparities in the social environment, however, social class does play an important role in creating intergroup boundaries in society. Understanding how social class shapes intergroup relations has important implications for how people relate across the class divide.

One important area of inquiry lies in research on class signaling. Though social class is not readily discussed in interpersonal encounters, signals of social class are visible in interactions (Bourdieu, 1979). In fact, research indicates that people accurately estimate the social class of others after watching only 60 seconds of a social interaction between strangers (Kraus & Keltner, 2009), and the same is true of accurate signaling of social class on online social networks such as Facebook (Kraus et al., 2013).

Moreover, in experimental research, signals of social class shape interactions in important ways. In some recent research, participants were assigned to wear their own clothing, sweat pants and a T-shirt purchased at Walgreens, or a business suit purchased at Macy's, before engaging in a scripted interaction with another participant who was completely unaware of the clothing change (Kraus & Mendes, 2014). Participants interacting with a person assigned to wear clothing that reflected a higher social class showed reduced subjective ratings of social power and physiological signs of threat vigilance (Kraus & Mendes, 2014). These initial results suggest that class signals change the ways in which individuals interact with and perceive others.

Given the power of social class signals to elicit changes in social interaction behavior and perception, it is reasonable to suggest that cross-class interactions are likely to lead to similar intergroup challenges as those occurring across gender and racial divides. In a series of studies testing how cross-class interactions fare relative to same-class ones, Côté and colleagues (2014) asked participants to engage in interactions with a person from either their same social class or a different one. Engagement within the interaction was measured using self-reports of liking and comfort, or with behavioral measures of genuine positivity (e.g., genuine smiles and laughs). Results across the studies indicate that people higher in social class are most engaged in interactions with upper-class interaction partners, whereas people lower in social class are most engaged in interactions with lower-class interaction partners (Côté et al., 2017). These results indicate that as people seek upward mobility in society, group processes related to belonging and identification influence, and possibly impede, how individuals from differing class background relate to each other.

Reducing Economic Inequality

Related to the psychological study of social class is the study of economic inequality, often conceptualized as the degree of disparity within a society between those at the top and bottom of the class hierarchy. How people perceive and respond to economic inequality has become an important topic in the psychological study of social class. Several lines of inquiry converge on the notion that as levels of economic inequality increase, indices of health and social problems also increase. In a meta-analytic review of the literature, this pattern was found in 70% of countries surveyed (Wilkinson & Pickett, 2006). Moreover, psychological research suggests that people prefer less unequal societies, as participants across several surveys prefer countries with lower levels of pay inequality (Norton & Ariely, 2011), especially between CEOs and average workers (Kiatpongsan & Norton, 2015). Importantly, these preferences also do not owe to utopian preferences for total equality, as people still prefer some level of inequality overall—thus, allowing the reward of exceptional work, talent, and effort (Norton & Ariely, 2011).

Despite the professed desire for a more equal society—and the manifest consequences of such inequality in the form of poor psychological health and functioning at the bottom of the hierarchy, research indicates several obstacles to reducing societal inequity. First, Americans seem to have widespread beliefs in terms of class mobility. Across several studies, actual estimates of real class mobility in society (e.g., the chance that a person would rise in income to the top 20% from the bottom 20% within his or her lifetime) were far lower than assessed beliefs about class mobility (Davidai & Gilovich, 2015; Kraus & Tan, 2015; Kraus, 2015). Motivation to reduce economic inequality is likely to stagnate if individuals believe that reaping the rewards of that inequality is possible for many Americans.

Second, beliefs in meritocracy and equality of opportunity appear to be strong in many societies (especially the United States) and appear to be strongest among those at the top of the class hierarchy. Compared to their lower-class counterparts, for instance, relatively higher social class individuals think of wealth and poverty as being caused by personal effort and skill rather than the social context (Kluegel & Smith, 1986; Kraus, Piff, & Keltner, 2009) and are more likely to think that social class is determined

by internal dispositions or genes (Kraus & Keltner, 2013; Mahalingam, 2003). Such beliefs are likely to reduce support for reducing economic inequality, because they suggest that disparities in wealth between the haves and the have nots are natural rewards for differing skill, talent, and effort.

Social Class within and across Cultures

Nations differ in terms of wealth, levels of economic inequality, citizens' attitudes toward inequality, and prevailing cultural norms in general. Thus, nations and cultures may differ in the extent to which social class affects individuals within a society—and may even produce different relationships among the variables altogether. On the other hand, social class itself—in some form or another—is probably a universal phenomenon (Hofstede, 2001). At least some phenomena, therefore, should reliably appear across cultures, even if cultures moderate their expression. Though truly cross-cultural research on the psychology of social class is scant, research that has either measured social class or connected concepts across cultures show both similarity and divergence in the psychological consequences of social class.

One robust finding within the United States on the psychology of social class is that of greater independence on the part of relatively upper-class individuals. Though little research directly tests whether these findings apply cross-culturally, the literature suggests that the relationship between social class and individualism is functionally similar across cultures. Cai, Kwan, and Sedikides (2012), for example, administered large-scale surveys in China—a collectivist culture—and measured, among other things, social class and narcissistic personality. Narcissism—characterized by exaggerated self-importance, confidence, and attention seeking—is a construct that is conceptually similar to cultural independence and, arguably, at odds with collectivism. Across two studies, the authors found that self-rated social class was positively associated with narcissism. Studies that directly compare the United States to more collectivistic cultures find similar patterns: I. Grossmann and Varnum (2011) measured social class (using parental educational achievement) and conceptions of the self (using an implicit measure) in samples from the United States and Russia. Russian

participants, unsurprisingly, scored higher on a measure of interdependence than did those from the United States, but participants from lower-class backgrounds in both the U.S. and Russian samples showed evidence of more interdependent conceptions of the self compared to upper-class participants.

Just as every nation will have some form of social class, every culture will have some degree of inequality, and even those at the bottom of the hierarchy need somehow to make sense of unequal distributions of resources (see, e.g., Hofstede, 2001 on “power distance”). For example, all individuals within a society seem to agree that higher-status individuals are more competent (Durante, Fiske, Kervyn, & Cuddy, 2013), which implies that even lower-class individuals implicitly accept the premise that those who are more successful enjoy their position for a reason. However, that all levels of society accept inequality (Jost, Banaji, & Nosek, 2004) does not imply that all within a society accept it the same way. As mentioned, upper-class individuals in the United States described inequality by appealing to dispositional explanations, while lower-class Americans appealed to contextual explanations (Kluegel & Smith, 1986; Kraus et al., 2009). Similarly, those of higher social class rank are more likely than those of lower rank to espouse “essentialist” theories of social class, the belief that a group owes its success to some aspect of its biology.

Similar research from India (a more collectivist and holistic society) suggests that those at the top and the bottom of the hierarchy view social classes much the way Americans do. For example, members of higher Indian castes believed that a child born into one caste and adopted into another would still exhibit behavior consistent with his or her birth caste, whereas lower-caste participants predicted the opposite (Mahalingam, 2007). Thus, individuals of high social rank endorsed more essentialist views regarding the child’s behavior (implicitly reasoning that those born into a higher caste are inherently different than others) and those of a lower social rank endorsed more social-constructivist explanations (reasoning that the child would adopt the customs of the adoptive caste).

Notably, cross-cultural patterns of attributions likely extend beyond issues of social class and inequality. Within a French sample, for example, those with higher occupational status were more likely to explain a frustrated cashier’s behavior in terms of the cashier’s disposition and temperament, while lower-class participants provided more contextual

explanations (Beauvois & Dubois, 1988). Similarly, I. Grossmann and Varnum (2011) asked participants in both the United States and Russia to make causal attributions about two fictional characters who committed socially desirable and undesirable actions. In both samples, lower-class participants were more likely than their upper-class counterparts to describe the protagonist's behavior in contextual terms.

On the other hand, the experience of social class also depends significantly on the culture within which social class is experienced. One such difference may lie in the way individuals within societies express higher social class. In one traditional village in Fiji, for example, cultural norms generally forbid the overt expression of pride, even in those with higher status (Tracy, Shariff, Zhao, & Henrich, 2013). Instead, pride is expressed through positive affect. Because of this, Fijian villagers were more likely to indicate images with smiling and happy participants as being associated with high status. Furthermore, in developing nations, increased obesity is associated with high wealth, whereas in more developed nations such as the United States, obesity is associated with lower wealth (Sobal & Stunkard, 1989).

Additionally, how individuals see themselves fundamentally shapes how they interpret their own achievements and stressors. Recall that individuals from Western societies evaluate the self and reflect on wellness in ways that conjure personal efficacy, agency, and accomplishments. In countries such as the United States, subjective social status is more important for self-evaluation than in Japan, where one's objective social status mattered more (Curhan et al., 2014a, 2014b).

Culture also has the power to shape how our relative socioeconomic standing makes us happy (or does not). Within developing nations, the relationship between subjective well-being (SWB) and income ($r = .20$) is larger than the relationship in already-developed nations ($r = .13$). Furthermore, the associations continue to diverge when looking at low-income regions of developing nations ($r = .28$), and high-income regions of developing nations ($r = .10$) (Howell & Howell, 2008). Taken together, these results support the notion that one's specific environmental context shapes his or her well-being. In particular, it suggests that income and wealth become more important for defining well-being in contexts where basic needs, such as food, clothing, stability, and a general ability to buffer oneself

and one's loved ones against the world's uncertainties is not guaranteed. Conversely, in environments where opportunities and advantages are abundant, education and financial security render income comparatively less important. Applying this principle to other domains may be fruitful in the cultural psychology of social class: That is, would differences in basic cognitive process due to social class, for example, be greater in countries where social class matters more for well-being and the fulfillment of basic needs? Future research on this question is warranted.

The psychological study of social class is emerging in cultural psychology. Within the confines of this burgeoning research tradition are potential answers to some of society's most pressing questions about health and well-being, economic justice, equality of opportunity, and biological determinism. As cultural psychologists continue to take the lead in the study of social class, new knowledge about how our basic psychology is magnified or diminished by our position on the social ladder of society will become enriched by theoretical perspectives that account for cultural beliefs and knowledge systems. Though definitive answers to these big questions are still far beyond the horizon, they grow closer and closer as the study of social class matures and advances into the future.

CHAPTER 28

Culture, Race, Ethnicity, and Personality

Rodolfo Mendoza-Denton and Frank C. Worrell

Despite vigorous debate about distinctions among the constructs of culture, race, and ethnicity, these constructs are often used interchangeably both in academic and popular discourse, and are often defined similarly in terms of socially shared and transmitted values, attitudes, and beliefs (Worrell, 2015). Independently, Mendoza-Denton and Mischel (2007) proposed values, attitudes, and beliefs as a foundation for understanding the way in which culture and person are co-constituted or “make each other up.” Our aim in this chapter is to show that race/ethnicity and person may also be understood as having a similar co-constitutive relationship, such that an individual’s personality cannot be understood outside or separately from his or her racial/ethnic upbringing. To concretize these arguments, we outline a framework that allows us to conceptualize the interrelationship among personality, culture, race, and ethnicity. We discuss research on racial identity attitudes, status-based rejection expectations, and their interactive effects as examples of constructs that are equal part person characteristics as they are constructs related to race and ethnicity.

The co-constitution of culture and psyche has come to be one of the core guiding principles of cultural psychology (Cole, 1996; Kitayama & Cohen, 2007). In this chapter, we apply this foundational premise of co-constitutionality to the relationship among the constructs of personality, culture, race, and ethnicity. Discussions of race and ethnicity often invoke the concept of culture, and there is a substantial literature and vigorous debate with respect to distinguishing these terms (e.g., Betancourt & López,

1993; Coleman, 2008; Helms & Talleyrand, 1997). Drawing on our prior work (e.g., Mendoza-Denton, Leitner, & Ayduk, in press; Worrell, 2015), and consistent with the premise of co-constitutionality, we argue here that what is often referred to as an individual's "personality" is deeply and inextricably shaped by the person's social and interpersonal context, which is itself a reflection of the person's cultural, racial, and ethnic milieu. We take the position that, at a psychological level, culture, race, and ethnicity are so similarly defined in the literature that they are functionally indistinguishable when we think about their impact on the personality system.

William James (1890) recognized that people have many different roles and personas, depending on the social/interpersonal environment. Cooley (1902, p. 152), in discussing the "looking glass self," posited that how others see us directly influences self and identity. George Herbert Mead (1934) argued that the sense of self is developed primarily by taking the perspective of others, and that mind emerges out of joint social activity. Together, these theoretical traditions anticipated the cultural-psychological notion that social and personality processes are intertwined. Here, we join this long tradition of interpersonal theories of personality (see also Bowlby, 1969, 1973, 1980; Erikson, 1950; Horney, 1937; Sullivan, 1953), adding a simple yet critical insight—that culture, race, and ethnicity are embodied within social interaction: the stigma people face from others, the prejudice that people impart on others, and the intergroup interactions that arise from the group differentiations we perceive (Markus & Hamedani, [Chapter 1](#), this volume). We offer here a framework that allows us to integrate race and ethnicity into our understanding of the person as a dynamic, thinking being that is, through and through, a reflection of the individual's social and cultural upbringing.

A FRAMEWORK FOR THE STUDY OF PERSONALITY IN CONTEXT

Studying the relationship among culture, race, and ethnicity on the one hand and personality on the other can be challenging: It requires reconciling group-level and individual differences. More specifically, group membership matters when studying race, ethnicity, and culture—groups vary in the

attitudes, beliefs, teachings, and values that they hold, share, and pass on. At the same time, not every group member has the same attitudes, values, and history. How, then, can one then integrate a group lens into the study of individual differences?

In what follows, we describe the cultural cognitive–affective processing system (C-CAPS; Mendoza-Denton et al., in press; Mendoza-Denton & Mischel, 2007), a framework that allows us to integrate social influences into the stable ways that people perceive, parse, and process information about their world. The C-CAPS proposes a dynamic network of information-processing units. The content of the units themselves, as well as their interconnections, are provided through social interaction (the principal vehicle through which acculturation occurs). The resulting network is the way in which the co-constitution of person and context are operationalized in the C-CAPS framework. The idea of co-constitution is at the heart of how environmental stimuli, in the form of culture, race, and ethnicity, come to be an inextricable part of the *person*.

Figure 28.1 illustrates the C-CAPS framework, which focuses on the mediating psychological processes that undergird perception and behavior. The large circle in the middle of the figure represents the individual person, while the smaller circles represent that individual's information-processing units: the person's expectations, beliefs, attitudes, goals, and self-regulatory competencies (see Mischel & Shoda, 1995, 2008). Connections among the units are represented either as solid (excitatory connections) or dotted (inhibitory connections) arrows. Note that this illustration is a highly simplified representation of what is clearly a much more complex network of units and interconnections.

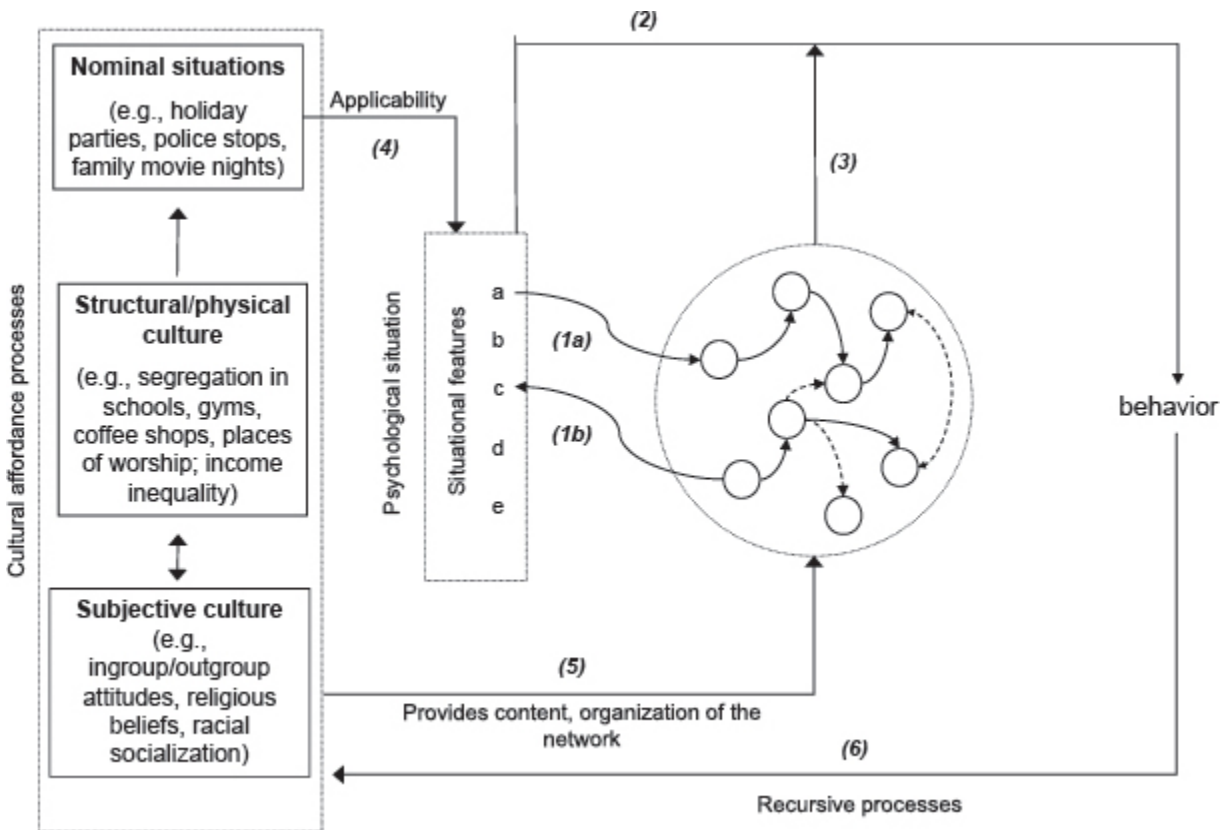

FIGURE 28.1. The C-CAPS framework.

Although the network is itself stable—part of what makes for stability in personality processes—specific features of situations can “turn on” or “turn off” any given activation pathway (Arrow 1a). As such, behavior is a function of not only the network but also the situation. For example, a person may be primed to expect, perceive, and strongly react to discrimination when being stopped by a police officer, but this stable dynamic may not be activated at all at a family holiday dinner. As research on race-based rejection sensitivity (Mendoza-Denton, Downey, Purdie, Davis, & Pietrzak, 2002) demonstrates, once expectations of discrimination are activated, such expectations influence the perception of the situation itself (Arrow 1b). The person’s psychological representation of the situation then has an effect on behavior (Arrow 2), although other units in the system also come into play to modulate the person’s response (Arrow 3), for example, when a person’s religious beliefs or well-rehearsed self-regulatory strategies come into play. Such patterns of activation, while stable and

characteristic of the person—and thus, describable as a feature of the individual’s personality—are not necessarily descriptive of the person’s behavior in other situations, in which another, equally characteristic pattern may describe the person (e.g., gregarious and extraverted at family parties).

Thus, although the network itself is stable, as the individual moves across different situations, different mediating units and their characteristic interrelationships become activated in relation to psychological features of those situations (the reader can imagine different “1a” and “1b” arrows activating or inhibiting subnetworks as a function of the situational features). Key to this analysis is the idea that given similarity in the way that certain groups of people are treated, certain stable dynamics (e.g., race-based rejection sensitivity) may be more likely to characterize members of certain groups (e.g., racially profiled minorities) over others.

Individual differences within this culturally infused system can emerge in at least two ways. The first lies in differences in the experiences one has, the messages one is exposed to, and the lessons one is taught—that is, at the level of the content of the units within the network. For example, not every member of a profiled group will in fact be profiled or stopped by police, leading to differences in the experiences and expectations group members might have. As another example, children receive different types of messages and strategies from their parents about coping with racism, a process termed “racial socialization” (Hughes et al., 2006). Individuals further differ in the frequency and degree to which they are exposed to racial socialization messages (Hughes & Chen, 1997; White-Johnson, Ford, & Sellers, 2010). Thus, even though two people may hold similar expectations of discrimination and perceive discrimination to similar degrees, a person who is racially socialized with messages of pride and preparation for bias may be less likely to experience negative mental health outcomes (Fischer & Shaw, 1999; Harris-Britt, Valrie, Kurtz-Costes, & Rowley, 2007; Neblett et al., 2008).

The second way in which individual differences can emerge within the C-CAPS is through differences in the network organization, that is, the interconnections between the individual differences themselves. To illustrate, Rheinschmidt and Mendoza-Denton (2014) have found that although individual differences exist among college students in their expectations of rejection on the basis of their social class, these concerns

interact with the students' general beliefs as to whether people's characteristics (including, presumably, their social class) can change. Rheinschmidt and Mendoza-Denton found that students who are concerned about rejection based on social class, but also believe that they are unlikely to change, are the least likely to endorse a belief that they can succeed through hard work and thus suffer academically.

Culture not only influences the content and relationship among the units within the network, but it also guides and constrains the social stimuli that the person is exposed to through what Kitayama and Markus (1999) referred to as "cultural affordances" (Arrow 5 in [Figure 28.1](#)). We group these cultural affordances into three subcategories based on our reading of the cultural-psychological literature—subjective culture, physical/structural culture, and nominal situations, and illustrate them at the left of [Figure 28.1](#). The shared beliefs, values, attitudes, and meaning systems of a cultural group are termed "subjective culture" (Triandis, 1980). Cultural groups can be defined at various levels: families, peer groups, communities, or nations. These cultural groups are clearly not mutually exclusive, and part of a person's individuality comes from the unique combination of social groups to which he or she belongs. Values, attitudes, and meaning systems, similarly, can be shared at the level of the family (e.g., respect for elders), the peer group (e.g., disdain for school), the community (e.g., ethnic pride), or the nation (e.g., freedom). Subjective culture can also be transmitted intergenerationally. Examples can include attitudes about ingroups and outgroups, one's religious beliefs, or racial socialization. Within-group heterogeneity can arise out of differential exposure to subjective culture at various levels.

The middle box within the left-hand rectangle in [Figure 28.1](#) recognizes structural/physical manifestations of culture. School or neighborhood segregation and income inequality are examples of structural culture; gyms, coffee shops, and places of worship are examples of physical culture. It is important to note that structural and physical culture arise from and serve to maintain cultural value systems (e.g., when stereotypes and discrimination lead to income inequality and segregated schools and neighborhoods). Subjective and structural culture then facilitate the specific nominal situations that people experience in their day-to-day lives. Nominal situations tend to be temporally discrete and relatively transitory

instantiations of the cultural milieu: holiday parties, police stops, family movie nights, and the like.

Any nominal situation is, of course, subject to the individual's appraisals, as Arrow 1b suggests in [Figure 28.1](#) (Major & O'Brien, 2005; Trawalter, Richeson, & Shelton, 2009; Pascoe & Smart Richman, 2009)—a “microaggression,” for example, may be readily interpreted as hostile by one person but as innocuous by another. At the same time, not all appraisals are equally applicable across situations, which makes some appraisals more likely than others in certain situations (Higgins, 1996; Arrow 4). The situation, as appraised, activates and inhibits other information processing units in the system (Arrows 1a and 1b), cascading through the network until behavior is generated (Arrows 3 and 4). The C-CAPS also allows for feedback loops (Arrow 6), in which the individual's own behavior influences situations to which the individual is likely to be exposed. For example, a woman who worries about being included in an engineering class might skip class or avoid office hours (e.g., Pinel, 1999), whereas another woman may decide to organize a movement to address such inclusion and shape the structural or physical culture (Mendoza-Denton & Mischel, 2007).

Tying C-CAPS to Social Interaction and Culture

Reminiscent of the work of social interactionists reviewed earlier, a wave of recent research (Carpenter, Nagell, & Tomasello, 1998; Haun, Rekers, & Tomasello, 2014; Over & Carpenter, 2009; Scott & Baillargeon, 2013; Tomasello, Carpenter, Call, Behne, & Moll, 2005; Tomasello & Herrmann, 2010; Woodward, 1998, 1999) suggests that culture itself arises out of social interaction. By identifying social interactions as a key mechanism through which culture develops, this research allows us to understand more deeply the relationship among culture, race, ethnicity, and personality. Tomasello and colleagues (2005) propose that humans may be biologically predisposed to participate in culture by virtue of three *skills of cultural cognition*: the ability to infer the intentions of others, to participate in shared activity, and to share a common goal or intention (shared intentionality). In other words, humans are inherently motivated to understand each other, to share goals, and to achieve these goals together. These ideas are consistent with

proposals for a fundamental human need to belong (Baumeister & Leary, 1995; Fiske, 2004), and to trust and understand one another (Fiske, 2004). These proclivities make the development of shared C-CAPS networks not only possible but also inevitable.

This research suggests that contents and organization of the C-CAPS network develop from birth through social observation, imitative learning, and joint activity. Joint activity and a motivation to understand one another provide the developing cultural creature with the motivation and the means to pick up a cultural group's values, goals, beliefs, attitudes, and "ways of doing."

Recall that cultural groups can differ in size, and that a person may belong to many cultural groups (Leung & Koh, [Chapter 21](#), this volume). The expansion of the individual's access to increasingly larger social groups is likely to be a developmental process, as the growing cultural being goes from interacting with the primary caretaker, to playgroups, peers, neighbors, communities, and so on. As the person's cultural groups grow in size and sophistication, shared intentions and goals are manifested through social norms, social values, and shared subjective culture (Gergen, 1993; Searle, 1995). Over the course of a lifetime, each individual's C-CAPS comes to reflect the unique amalgamation of his or her social experiences, a unique historical blueprint of his or her social interactional history. We note that this view of personality is closely aligned to Sullivan's (1953) vision of personality as the total of that person's social interactions. However, by considering shared expectations, values, beliefs, goals, and attitudes, the C-CAPS helps us make a theoretical leap to how culture, race, and ethnicity can come to be co-constituted with the personality system.

We note that although the C-CAPS framework emphasizes the social and cultural environment as a primary determinant of the contents and organization of the network, we do not claim that humans are a *tabula rasa* at birth, devoid of species-specific orientations and even temperamental differences (e.g., Buss & Plomin, 1984; Kagan, 1989; Rothbart & Derryberry, 2000; Kashima, [Chapter 2](#), and Mesoudi, [Chapter 5](#), this volume). As discussed earlier, Tomasello's skills of cultural cognition, conceptualized as biological predispositions that humans come into the world ready to deploy, are an integral part of what leads to the development and maintenance of culture. Similarly, Fiske (2004) identified a set of five "core" human motives

(belonging, understanding, controlling, enhancing self, trusting) that influence behavior. In fact, Fiske views belonging as the cardinal motive, consistent with other scholars who view the need to belong as a primary motivation for human beings (Baumeister & Leary, 1995; Kim & Lawrie, [Chapter 10](#), this volume). The skills of cultural cognition can be thought of as existing in the service of these theoretically derived core needs.

Culture, Race, and Ethnicity

In prior sections, we have reviewed C-CAPS, an approach to personality that proposes expectations, values, goals, beliefs, and attitudes as the central mediating units of a personality system that, while itself stable, leads to different behaviors depending on the situation and the network of activation within the system. In the next section, we argue that definitions of culture, race, and ethnicity show a surprising degree of convergence with the social-cognitive units that constitute the C-CAPS network, suggesting that the influence of these forces on the person is through these variables. The link to social interaction becomes critical as we move from culture toward a discussion of race and ethnicity, given that these influences on C-CAPS also reflect a sense of group identity.

Culture

Although culture has been defined in several ways (Jahoda, 2012), definitions of “culture” typically include values, beliefs, knowledge, attitudes, and behavioral traditions (Mendoza-Denton & Mischel, 2007; Worrell, 2015). The *APA Dictionary of Psychology*, for example, defines culture as “1. The distinctive customs, values, beliefs, knowledge, art and language of a society or community [and] 2. the characteristic attitudes and behaviors of a particular group within society, such as a profession, social class, or age group” (VandenBos, 2007a, p. 250). Frisby (1992, pp. 533–534) identified six dimensions of culture used in everyday language: (1) “characteristics patterns of living, customs, traditions, values, and attitudes”; (2) “significant artistic, humanitarian, or scientific achievements” of one’s ancestors; (3) the “common set of attitudes and beliefs” that guide one’s “feelings about,

interests in, or identification with members of one's group"; (4) "values and norms of the immediate [socialization] context"; (5) "superficial differences . . . in such characteristics as popular clothing or fashion styles, music or dance styles, styles of religious worship, culinary traditions, or speech and language styles"; and (6) "differences in physical appearance." Multiple definitions of culture in the literature (e.g., Atkinson, 2004; Hofstede, 2001; Smith, 2003; Triandis, 1994) touch on very similar themes, all converging on shared values, attitudes, belief systems, patterns of thought, and behavior. The similarity to the cognitive–affective units proposed for the personality system in C-CAPS is clear.

When culture is conceptualized in these terms, we also recognize a link to a literature on social identity. This is important, because it is through identity that culture as race and ethnicity is manifested. For example, when thinking of "Latino/a culture," "black culture," or even "university culture," people tend to think of the shared social identity, along with the characteristic cognitive–affective units associated with this immediate socialization context. Indeed, physical manifestations of culture, such as music, cuisine, and dress, are also associated with group identification (and social interaction). We return to this point later.

Ethnicity

King (2002, p. 247) defined ethnicity as "a sense of peoplehood and commonality derived from kinship patterns, a shared historical past, common experiences, religious affiliations, language or linguistic commonalities, shared values, attitudes, perceptions, modes of expression, and identity." The *APA Dictionary of Psychology* defined ethnicity as "a social categorization based on an individual's membership of or identification with a particular ethnic group" (VandenBos, 2007b, p. 345), and Coleman (2008, p. 1137) defined ethnicity as "a social category defined by the shared historical, national, social, political and cultural heritage of a people . . . [and] includes a reference to shared ancestry language, customs, traditions, and similar physical characteristics among a group of people." Similarly, *Dictionary.com* (n.d.-a) defines ethnicity as "a social group that shares a common and distinctive culture, religion, language or the like." As these

examples illustrate, definitions of ethnicity have considerable overlap with definitions of culture (and, in some cases, use culture to define ethnicity). Note, for example, that King's (2002) definition of "ethnicity" and Vandenbos's (2007a) definition of "culture" are essentially interchangeable.

Race

Although some definitions of race emphasize common roots in blood lineage or phenotypic similarity that include skin color, hair, and facial structure (e.g., Reber, 1985), such definitions have proved problematic given conclusive evidence indicating greater within-group than between-group variability among racial groups, considerable fuzziness in the boundaries that might distinguish one racial group from another, and no sharp boundaries between racial groups (see Mendoza-Denton & Mischel, 2007; Teo, 2009). Indeed, given the difficulty of mapping biological markers consistently to racial categorizations, the American Anthropological Association has disavowed defining race as a biological construct (Zack, 2001). More recently, definitions of race place a much stronger emphasis on the social construction of race, acknowledging that phenotype is related to race primarily through social construction (in line with our analysis, we note that a similar use of "phenotype" can easily characterize definitions of culture and ethnicity). As a result, recent definitions of race include elements that are also present in definitions of culture and ethnicity, including shared ancestry and customs (e.g., Gotanda, 2011; VandenBos, 2007c). Among the definitions that *Dictionary.com* (n.d.-b) provides for race, for example, are "1. a group of persons related by common descent or heredity; 2. a group of tribes or peoples forming an ethnic lineage, and 3. any people united by common history, language, cultural traits, etc." Thompson (2008, p. 1279, emphasis added) defined race as "a label that is commonly ascribed to individuals in certain societies based on their *affiliation with a group of people*. Members of racial groups typically share common characteristics in physical appearance or phenotype, but more significantly, they share a *common stature within a given society*."

There is a long-standing debate in the research literature as to whether culture, race, and ethnicity refer to different constructs (see, e.g., Betancourt

& López, 1993; Coleman, 2008; Phinney, 1996; Helms & Talleyrand, 1997; Umaña-Taylor et al., 2014; Worrell, 2015). We opt here to take a fresh approach: Rather than try to distinguish among them, we recognize a common “core” that centers around shared values, beliefs, practices or habits, attitudes, and group affiliation. We also underscore the similarity of these variables with the social-cognitive units that have been posited for the C-CAPS personality framework. As with a prior analysis of culture and personality (Mendoza-Denton & Mischel, 2007), we note that these units provide a bridge to understanding the co-constitution of race, ethnicity, and person within a unified theoretical framework that privileges social relationships as its principal vehicle.

TWO ILLUSTRATIONS: RACIAL/ETHNIC IDENTITY AND STATUS-BASED REJECTION SENSITIVITY

In the section that follows, we briefly illustrate some ways in which the C-CAPS framework operates specifically through the exploration of two individual-difference constructs: racial/ethnic identity, status-based rejection sensitivity, and their interactive relationship. We choose these constructs (and their interaction) as broad examples of how it is possible to understand race and ethnicity within the C-CAPS framework. These examples are clearly not exhaustive; the analysis could fruitfully be extended to other constructs. The emphasis in these examples is in providing a deeper understanding of how sociocultural history, social relationships (both positive and negative), and contextual constraints shape the thoughts, cognitions, and affects that individuals experience, vis-à-vis the experience of race/ethnicity in the U.S. context. Elsewhere, we apply the C-CAPS framework to cultural differences in behavior (Mendoza-Denton & Mischel, 2007), health disparities (Mendoza-Denton & Leitner, 2017), and interpersonal relations (Mendoza-Denton et al., in press).

Racial and Ethnic Identity

Worrell (2015) contended that culture, race, and ethnicity are all defined in terms of three common characteristics:

1. Ascribed membership in a specific societal group, so we can refer to blacks in the United States, and mean the black “race,” black culture, or individuals of African descent in the United States, who come from several different ethnic groups.
2. A sense of affiliation or affinity with the group, so that individuals acknowledge and accept that they are members of a group with a shared historical past.
3. Shared values and beliefs based on their group membership, an assumption that is made both by group members and by nonmembers of the group, in spite of intra-group differences. (p. 254)

These three commonalities in turn bring to mind Tajfel and Turner’s (1979) classic definition of “social identity” as that part of the person’s self-concept that involves (1) the recognition that one belongs to the group, (2) placing a value in that group membership, and (3) having an emotional investment in that membership.

The overlap of Worrell’s (2015) view of race and ethnicity as culture and Tajfel and Turner’s (1979) classic definition of social identity is intentional, as Worrell specifically sees the cultural influence of race and ethnicity, at a psychological level, as operating through social identity. As Worrell (2015) wrote, “Whereas race and ethnicity are social constructions, their psychosocial manifestations are racial and ethnic identity, respectively. Thus, culture, racial identity, and ethnic identity are members of the same family” (p. 254). This integrated viewpoint is not heretical. For example, in a recent report from a Society for Research in Child Development workgroup, Umaña-Taylor et al. (2014, p. 23, emphasis added) noted:

A racially Black Dominican adolescent may reflect on her experiences of *racial* oppression in the United States, her *ethnic* heritage from the Dominican Republic, and the *cultural* traditions (e.g., Spanish language) that have been passed down when identifying as Dominican. . . . There are important cultural features associated with an individual’s identification with being African American that are lost when the identity is considered *racial* and not *ethnic* or *cultural*.

Consistent with our analysis so far, the influence of culture, race, and ethnicity on the person is deeply interpersonal, an active process of achieving and accepting shared worldviews into the self-concept, of monitoring one’s belonging in different social circles, and achieving an integrated sense of personal and group identity.

Erik Erikson's (1950, 1958) classic psychosocial theory of identity specifically posited that identity is affected by sociocultural, historical, and political events. He identified the formative role that discrimination can have on identity, noting that among stigmatized groups, "the widespread pre-occupation with identity . . . may be seen not only as a symptom of 'alienation' but also as a corrective trend in historical evolution" (Erikson, 1968, p. 297). The recognition that oppression and stigmatization play a formative role in the development of the self-concept, and in the formation of a collective identity (see Branscombe, Schmitt, & Harvey, 1999), is illustrated well in research on racial and ethnic identity.

Group identification is a multifaceted construct, and researchers disagree as to how many facets or components comprise the proper measurement of a social identity. Sellers and colleagues, for example, developed the Multidimensional Inventory of Black Identity (MIBI; Sellers, Rowley, Chavous, Shelton, & Smith, 1997; Sellers, Smith, Shelton, Rowley, & Chavous, 1998), which assesses seven aspects of African American identity along three dimensions: Centrality, Ideology, and Regard. Centrality refers to the degree that a person sees his or her race as a defining aspect of his or her self-concept; Ideology refers to the person's beliefs and attitudes about how group members should behave toward the ingroup and outgroups; and Regard captures the affective dimension in terms of how self and others judge one's race. The seven subscales of the MIBI include a Centrality subscale, four Ideology subscales, and two Regard subscales. Scores on versions of the MIBI have been examined in adolescents (Scottham, Sellers, & Nguyễn, 2008), emerging adults (Hurd, Sellers, Cogburn, Butler-Barnes, & Zimmerman, 2013), and adults (Street et al., 2012), and have been found to be related to psychological well being (Hurd et al., 2013) and to cultural constructs (Bryant, 2011). Sellers et al.'s model, although developed for African Americans, has been applied to other minority groups, as well as to majority group members (e.g., Casey-Cannon, Coleman, Knudtson, & Velazquez, 2011; Rivas-Drake, Hughes, & Way, 2009), suggesting that the Centrality, Ideology, and Regard dimensions of the MIBI may be applicable beyond black populations.

A second multidimensional instrument of black identity is the Cross Racial Identity Scale (CRIS; Vandiver et al., 2000; Worrell, Vandiver, & Cross, 2004), which is based on the expanded version of nigrescence theory

(NT-E; Cross & Vandiver, 2001; Worrell, Cross, & Vandiver, 2001). NT (Cross, 1971) was originally proposed as a developmental, linear stage model in the tradition of Piaget (1962) and Erikson (1950), with the notion of crises to be resolved or overcome. The original nigrescence model (NT-O) emerged around the Black Power movement of the 1960s (Worrell, 2008a), which, much like the Black Lives Matter movement, was as much a political as a sociocultural movement (Altman, 1998; Smith, 2003).

NT-O, in its original formulation, postulated five developmental stages: Preencounter, Encounter, Immersion–Emersion, Internalization, and Internalization–Commitment. Stage 1, Preencounter, is characterized by low or negative race salience; African Americans in this stage were thought to adopt the cultural worldview of European Americans, including negative stereotypes about their race. Cross (1971) associated this stage with self-hatred and low self-esteem. The African American individual in Preencounter uses European Americans and their culture as the normative social reference group, and progression through the stages represents changing one's cultural frame of reference, as well as one's understanding of what being of African descent means in the social context of the United States. The person moves into the Encounter stage following an experience or event that helps him or her realize that he or she is no longer able to ignore or shun group membership; the Encounter stage begins a process of identity exploration and is often associated with intense emotion.

NT-O postulates that the early search for racial identity leads to an immersion into and idealization of black culture, including history, literature, and customs, coupled with denigration of white culture. NT-O refers to this stage as Immersion–Emersion. Internalization, the fourth stage, occurs when the individual is able to celebrate his or her black identity without denigrating white culture, and the fifth stage (Internalization–Commitment) involves a commitment to action aimed at helping the black community. Movement across the five stages is a journey toward self-acceptance as a black being. The model, in many ways, echoes the very aims of the social movement in which it was conceptualized; it embodies a cultural transformation reflected in a psychological transformation: “The process should be viewed as the *Afro-American model for self-actualization under conditions of oppression*” (Cross, 1971, p. 25, emphasis added). Culture and person make each other up.

Despite the elegance of this developmental model, however, data have not supported a developmental stage conceptualization of racial identity (Worrell, 2012). Several studies show no consistent relationship between racial identity attitudes and age (Neil, 2003; Parham & Williams, 1993; Plummer, 1996), and Worrell (2008b) found no evidence for a developmental progression of racial stages in a study of racial identity attitudes across three developmental periods. Instead, researchers now widely agree that black identity is better conceptualized as a collection of worldviews (Helms, 1986) or attitudes and beliefs (Cross, 1991). This shift brings the “active ingredients” of racial identity in line with those of the C-CAPS.

In NT-E (Cross & Vandiver, 2001; Worrell et al., 2001), the most recent version of Cross’s theoretical formulation, black racial identity is conceptualized as a series of attitudes rather than a set of stages. According to NT-E, “Black racial identity refers to a set of attitudes held by individuals of African descent, and includes how these individuals view (a) themselves as Blacks, (b) other individuals of African descent, and (c) individuals from other racial and ethnic groups” (Worrell, Mendoza-Denton, Telesford, Simmons, & Martin, 2011, p. 637). NT-E postulates eight attitudes, each of which captures one aspect of what it means, psychologically, to be African American. In NT-E, the stages from the original theory are interpreted as three broad thematic categories: Preencounter, consisting of low or negative race salience; Immersion–Emersion (identity in flux), and Internalization (or the reconciliation of one’s identity alongside other identities). Within each of these themes, a number of attitudes have been identified: Assimilation, Miseducation, and Self-Hatred for Preencounter, Anti-White and Intense Black Involvement for Immersion–Emersion, and Afrocentrism, Biculturalism, and Multiculturalism with respect to Internalization.

One of the consequences of conceptualizing racial identity as attitudes rather than stages is that it allows for the recognition that an individual can simultaneously hold attitudes that are not necessarily congruent, such as when a person endorses both miseducation attitudes and Afrocentric attitudes (such a profile might be considered to be conflicted; Telesford, Mendoza-Denton, & Worrell, 2013). Indeed, research shows that racial identity *profiles* or *clusters* are more reliable indicators of psychological functioning than racial identity scores on individual subscales (Telesford et

al., 2013; Worrell, Andretta, & Woodland, 2014). To date, researchers have identified several profiles, including Afrocentric, Anti-White, Assimilated, Conflicted, Intense Black Involvement, Low Race Salience, Miseducated, Multiculturalist, Negative Race Salience, and Self-Hating. From the point of view of the C-CAPS, it is worth noting that these profiles are not only applicable to African Americans as a group, but they also depict within-group heterogeneity and individual differences. Criterion validity for these profiles has been established: Chavez-Korell and Vandiver (2012) found that individuals in the Intense Black Involvement and Afrocentric clusters reported meaningfully higher scores on preference for black culture than individuals in the Multiculturalist, Self-Hatred, and Assimilation clusters. The findings were similar for social distance from mainstream culture, with some profiles indicating a strong preference for mainstream culture, others indicating a preference against mainstream culture, and with the Multiculturalists indicating a preference neither for or against mainstream culture.

Beyond African Americans

A widely adopted measure of group identity that is not specifically tailored to the African American experience is the Multigroup Ethnic Identity Measure (Phinney, 1992; Phinney & Ong, 2007), which is intended to capture Marcia's (1966) notion of identity exploration and identity commitment. Leach and colleagues (2008) have proposed a group-general hierarchical model of group identification in which self-definition and self-investment represent two superordinate axes along which group identification is organized. Nonetheless, Leach et al. also proposed several subcomponents within these two axes, including self-stereotyping, ingroup homogeneity, satisfaction, centrality, and solidarity. Although differences in the conceptualization and measurement of group identification can be difficult to reconcile, Worrell's (2015) emphasis on the importance of group membership and emotional investment in that identity do seem to emerge as relatively consistent themes in this literature, as Leach and colleagues (2008) recognize.

Consistent with the theme that there may be generality in the structure of racial identity across groups, Worrell, Mendoza-Denton, & Wang (2017) have recently validated scores on a new scale, the Cross Ethnic–Racial Identity Scale—Adult (CERIS-A; Worrell, Vandiver, Cross, & Fhagen, 2016) that can be used across different ethnic/racial groups. Worrell and colleagues find that that assimilation, miseducation, self-hatred, anti-dominance, ethnocentricity, multiculturalist inclusive, and salience meaningfully map the racial/ethnic attitudes of not only African Americans but also Asian Americans, European Americans, and Latinx Americans. By mapping the similarity in the psychological experience of African Americans (which most researchers have studied under a racial identity frame; see Cokley, Caldwell, Miller, & Muhammad, 2001) and Latinx and Asian Americans (which most researchers have studied under an ethnic identity lens; see Cokley & Vandiver, 2012), Worrell and colleagues (2017) further strengthen the proposition that race and ethnicity can be understood in terms of similar psychological processes.

As noted previously, there is a growing trend to recognize similarities among race, ethnicity, and culture. Umaña-Taylor and colleagues (2014, p. 23) suggested that the term “racial–ethnic–cultural identity” may more accurately capture identity processes, in the sense that people do not separate these components from one another in their lived experience as group members. Umaña-Taylor and colleagues defined ethnic–racial identity (ERI) as “a multidimensional, psychological construct that reflects the beliefs and attitudes that individuals have about their ethnic–racial group memberships, as well as the processes by which these beliefs and attitudes develop over time” (p. 23). Noting once again the explicit mention of the core mediating units proposed for the C-CAPS, we propose here that these identity processes are *also* descriptive of a process that can be characterized as *personality development*—racial–ethnic–cultural identity is an integral part of who we are.

Status-Based Rejection Sensitivity

“Like diamonds,” writes the author Denene Millner (2017), “Blackness is created under extreme pressure and high temperature, deep down in the

recesses of one's core," arguing why Rachel Dolezal (a former National Association for the Advancement of Colored People [NAACP] leader who was revealed to be white) can never be black. This quote underscores that the psychology of minority-group membership is deeply rooted within the group's own context and historical background, an important part of which is a history of stigmatization and the continuing discrimination that exists to this day (Sellers, Caldwell, Schmeelk-Cone, & Zimmerman, 2003; Shelton, 2000). This history, as well as prior experiences, are likely to affect individuals and their sense of self in profound ways (Humphreys & Kashima, 2002; Mischel & Morf, 2003; Kashima et al., 2004). These experiences are likely to also forge the stable responses that the individual marshals in response to discrimination. One such response pattern has been termed "race-based rejection sensitivity" (RS-race; Mendoza-Denton et al., 2002; Mendoza-Denton, Page-Gould, & Pietrzak, 2006), a process that also illustrates the intricate co-constitution of culture (societal stereotypes and prejudice), nominal situations (e.g., historically, white institutions), and the person (the RS-race dynamic itself). Beyond race per se, the construct of status-based rejection sensitivity is useful for understanding how experiences of discrimination can relate to social-cognitive processes.

The construct RS-race grows out of developmental perspectives on attachment (Bowlby, 1969, 1973, 1980) and rejection sensitivity (Downey & Feldman, 1996). Downey and Feldman proposed and have found support for the idea that when people experience rejection from parents, peers, or other important figures in the form of abuse or neglect, they are vulnerable to developing anxious expectations that they will be subject to rejection in new situations in which rejection is both applicable and salient (Higgins, 1996). Anxious rejection expectations provide a good illustration of how even though such expectations are stable within the individual and may be characterized as a disposition, they only become activated specifically in relation to features of the situations. To illustrate, Ayduk, Downey, Testa, Yen, and Shoda (1999) found that when rejection-sensitive women were rejected, they badmouthed the rejector; however, when there was a benign, alternative explanation for the rejection, rejection-sensitive women did not retaliate. Illustrating the cascading nature of the C-CAPS activation patterns, expectations lower the threshold for perceiving the rejection, and once the

rejection is perceived, intense, hot reactions to the perceived rejection follow.

To the degree that affiliation and acceptance can be considered fundamental human motives (Fiske, 2004), people may be universally capable of developing the dynamic of rejection sensitivity (anxious expectations → ready perceptions → hot reactions) if rejected or neglected. However, the manifestation of rejection may be expressed in many different ways that are constrained by socialization, which depends on one's social environment as well as people's group memberships. Mendoza-Denton and colleagues (2002) postulated that rejection can occur on the basis of not only idiosyncratic characteristics but also a devalued group membership—such as gender, sexual orientation, or race.

Cultural influences come into play at several levels. First, as has been widely recognized, stigma is context-specific—being Latino may be devalued in the classroom, but might be perceived as an asset on the soccer pitch (Crocker, Major, & Steele, 1998). As such, context can play a large role in determining whether a person develops RS-race; a gifted Latino *futbol* player may be exposed to few or no instances of discrimination and not develop a stable RS-race dynamic as a result. Second, even when two groups might be negatively stigmatized, the situations in which their stigma is applicable may be different. In the United States, for example, being African American carries a suspicion of low academic ability (Steele, 1997) but high athletic ability, whereas the reverse is true of Asian Americans (Chan & Mendoza-Denton, 2008). Thus, although two people may be equally apprehensive about their group membership, different situations are likely to activate their rejection concerns. Finally, the coping mechanisms marshaled in response to the rejection may be different—again, one's cultural group provides one with culture-specific, culturally appropriate strategies, and values, marshaled in response to rejection, as we noted earlier with respect to research on racial socialization.

Taking a cultural-psychological analysis seriously, assessments of rejection sensitivity in its various manifestations are not context general. Mendoza-Denton et al. (2002) conducted focus groups to discern the types of situations that activate race-based rejection concerns among African Americans, and constructed a questionnaire based specifically on those situations. Scenarios that activate race-based rejection concerns for African

Americans, for example, include ones involving racial profiling or potentially disparate treatment in the classroom—situations that contain “active ingredients” for making discrimination applicable and salient among this group (as it turns out, many of these situations are also applicable to discrimination for Latinx individuals, who suffer from similar treatment; Page-Gould, Mendoza-Denton, & Tropp, 2008). As expected, African Americans tended to score highest on the original RS-race measure, whereas European American and Asian American participants scored low on the measure and did not differ.

It is illustrative to note that although Asian Americans score low on the RS-race measure for African Americans, this is to be expected, because this questionnaire does not activate their concerns. Chan and Mendoza-Denton (2008) found that needing to ask for directions or asking people to repeat something they mumbled might be the activating features for Asian Americans, and when a questionnaire about anxious expectations of group-based rejection includes those situations, Asian Americans score much higher, and individual differences in such anxious expectations become diagnostic.

Among African Americans, individual differences in anxious expectations of race-based rejection have been found to predict students' GPAs. This finding illustrates the interplay between culture and individual differences that the C-CAPS model tries to capture. People's anticipatory, emotional, and behavioral dynamics vis-à-vis discrimination (the RS-race dynamic) are reinforced and maintained by the broader subjective culture (e.g., stereotypes, racism) and physical culture (majority-dominated college settings), as well as nominal settings (unequal opportunities). Rather than being a question about explaining the phenomenon either through social or personality psychology, this approach shows not only their inseparability, but the indispensability of their interplay for an understanding of the dynamic.

By contrast, RS-race among Asian Americans is unrelated to GPA (since the stigma of being Asian American does not involve questions about intelligence or academic ability) but negatively related to self-esteem. This relationship between status-based rejection sensitivity and feelings of self-worth for Asian Americans is also reflective of broader cultural dynamics. RS-race scores are *unrelated* to self-esteem among African Americans, and

tellingly, African Americans have had a collective consciousness-raising movement—namely, the Civil Rights Movement—that has made racial prejudice chronically accessible as an explanation for negative outcomes that might otherwise harm self-esteem (see Twenge & Crocker, 2002, for historical data supporting this view). Asian Americans have not had a similarly powerful collective social movement in the United States.

As these examples illustrate, even though the dynamic may in some ways be similar across groups, it is important to know the context, the history, and the situations to understand more fully the cultural manifestation of the personality dynamic. It is also important to understand the person *as an individual* to understand the expression of a cultural dynamic, as no two individuals within one group (e.g., Asian Americans) are going to respond to perceived rejection in exactly similar ways. To underscore the point just made about different outcomes being relevant for different groups, rejection sensitivity based on being gay (Pachankis, Goldfried, & Ramrattan, 2008) is related to internalized homophobia and risky sexual behavior, including sexual compulsivity (Pachankis et al., 2015) and decreased condom use (Wang & Pachankis, 2015).

Stigma consciousness (Pinel, 1999) is a related individual-differences construct that also taps into discrimination concerns. Brown and Pinel (2003) defined “stigma consciousness” as variations in how chronically self-conscious people are about their stigmatized status, which Pinel (1999) links to expectations about being the target of stigma. The Stigma Consciousness Questionnaire asks respondents to indicate their level of agreement to general items that include, for example, “When interacting with men, I feel like they interpret all my behaviors in terms of the fact that I am a woman” and “Stereotypes about women have not affected me personally” (reverse-scored). Research on stigma consciousness (e.g., Pinel, 1999; Schmalz, 2010) suggests that individuals who are chronically threatened about the possibility of discrimination may cope with aversive threat by avoiding activities or situations that activate their stigma-related concerns (e.g., the gym), even if these activities are health promoting.

Research both on stigma consciousness and status-based rejection sensitivity nicely illustrates the notion inherent in the C-CAPS framework that despite being dispositional or chronic, expectations of discrimination have to be *applicable* to the situation for the individual difference to affect

behavior (Arrow 4 in [Figure 28.1](#)) (see also Oyserman & Yan, [Chapter 20](#), this volume). Brown and Pinel (2003), for example, demonstrated that in a situational context of stereotype threat, individuals higher in stigma consciousness performed lower on a math test, but stigma consciousness was unrelated to performance in a context in which their identities were not threatened. Similarly, Mendoza-Denton, Goldman-Flythe, Pietrzak, Downey, and Aceves (2010) presented African American students with either positive or negative feedback under conditions in which they thought their race was either known or not known by their evaluator. The researchers employed this 2×2 design, overlaying the additional factor of RS-race. The results revealed that participants higher in RS-race who thought their race was known tended to mistrust the academic feedback they were given, regardless of whether such feedback was positive or negative. By contrast, participants who were low in RS-race tended to trust in the fairness of their evaluators, and their self-esteem therefore rose or fell depending on the valence of the feedback. In other words, when RS-race was not applicable (i.e., when the participants thought that their race was not known by the evaluator), this individual difference had no effect on the participants' trust of the evaluator or the feedback.

INTERACTIVE EFFECTS OF RACIAL/ETHNIC IDENTITY AND RS-RACE

So far, we have reviewed two culturally infused processing dynamics—social identification and status-based rejection sensitivity—and how their dynamics play out within the C-CAPS network. These dynamics, although both are stable aspects of the individual (and thus characterizable as individual differences), are also inextricably tied to the person's socialization as a member of a social group. Individual differences can develop as a function of different socialization experiences, for example, when RS-race develops from prior experiences of being rejected on the basis of group membership. In the case of social identity, individuals can hold different “buckets” or collections of attitudes related to themselves as racial–ethnic–cultural beings, and although it is possible to find some of the more

common profiles of such attitudes (Worrell et al., 2014), idiosyncratic patterns will always exist.

We noted earlier in this chapter that a second way in which individual differences develop within the C-CAPS system lies in the recognition that individuals are also characterized by multiple personality dynamics, which can themselves interact in different ways and moderate each others' influences. At present, our discipline does not possess the ability to model more than a handful (at best) of such dynamics operating at the same time; the complexity of such a task mirrors the complexity and uniqueness of individual humans. Nonetheless, we illustrate this complexity with a relatively simple example: How might racial/ethnic identity and RS-race, the two constructs we have covered here, interact? Although this question cannot address the level of complexity that would account for all of the variance in human behavior, the example does illustrate the need to understand that individual differences are embedded not only within cultural context but also within a network of other dynamic processes.

In understanding how racial/ethnic identity and status-based rejection sensitivity interact, it is interesting to note that in the literature on racial/ethnic identity, the literature has historically been somewhat equivocal on its relationship to academic adjustment. On the one hand, some scholars, notably Ogbu (1978, 1989), might suggest that having a strong minority cultural identity can be a risk factor for academic achievement, because such an identity is incompatible with a school-based identification and therefore becomes oppositional. By contrast, other research strongly suggests that cultural identity (in this case, a strong racial-cultural identity) is associated with positive educational outcomes and success, noting that a strong sense of one's culture and history serves as a source of strength and grounding for the individual (e.g., Oyserman, Kimmelmeier, Fryberg, Brosh, & Hart-Johnson, 2003; Yasui, Dorham, & Dishion, 2004). Mendoza-Denton and Page-Gould (2008) tested the hypothesis that both of these ideas may be correct, depending on the individual's level of RS-race. Specifically, they tested, and found support, for the idea that when an individual has reason to believe that his or her group membership is not safe within a given educational institution (as evidenced by high levels of RS-race), a strong ethnic identity should, in fact, develop in

opposition to a strong institutional identity given that the institution serves more or less as the rejector of that social identity.

By contrast, when a person has reason to believe that his or her social identity is safe within the context of the institution, then that person's high racial/ethnic identity should be able to serve a boosting function. Across a series experimental and field studies, Mendoza-Denton and Page-Gould (2008) found exactly this pattern. This very same prediction has been proposed by Byrd and Chavous (2012) in their person–context congruence model. Byrd and Chavous (2011, 2012) resolved the contradictory patterns of racial identity on academic achievement by hypothesizing that identity will have positive effects when the school context is congruent with the student's beliefs about their group. Consistent with Mendoza-Denton and Page-Gould's (2008) findings, Byrd and Chavous (2011, 2012) showed that in the context of a positive racial climate in the educational institution (as it relates to both peers and teachers), youth who also held their racial group in high regard (private regard) had higher levels of intrinsic motivation in the school setting. Among college students, Byrd and Chavous found that students high in positive regard, who felt that different racial groups were able to be interdependent and to value each other, had greater school satisfaction.

Nevertheless some peculiar findings arise: Students who are low in private regard showed greater academic satisfaction if they perceived strong institutional norms for positive intergroup contact—a pattern reminiscent of the finding from Mendoza-Denton and Page-Gould's (2008) studies in which those high in RS-race and low ethnic identity also showed relatively high academic success. These last findings suggest that people who are fearful of race-based rejection but do not identify with their social group, or who themselves may hold negative stereotypes about their group, may show an adaptation pattern akin to John Henryism (a type of “high effort” coping that may be associated with negative health consequences among African Americans; S. James, Hartnett, & Kalsbeek, 1983; also Bennett et al., 2004; Subramanya et al., 2013). These findings converge in reconciling different patterns of racial identification on academic achievement by noting that the patterns are moderated by people's sense of the racial climate in their institution (either through RS-race or through context). More broadly, they remind us that individual differences can lead to different outcomes

depending on other units–subnetworks–dynamics within the CAPS system. Again, our point here is not to exhaust the possibilities with respect for how to think about the relationship between race, ethnicity and personality, but to illustrate how the broad principles of the C-CAPS can help us understand individual differences and reconcile them with group-level commonalities and dynamics.

SUMMARY

In this chapter, we have reviewed how the “skills of cultural cognition” that may be unique to humans provide the foundation for shared goals, values, beliefs, and expectations (Gergen, 1993; Harris & Sadeghi, 1987; Tomasello et al., 2005; Searle, 1995). These shared intrapsychic variables, however, also exist outside of the interactants themselves, residing within subjective culture and structural physical culture, as habits, rites, and institutions (Geertz, 1973; Obeyeskere, 1981; Triandis et al., 1980; Tomasello et al., 2005). Bridging these ideas with the foundational premise of co-constitution between person and culture (Shweder, 1990; see also Kitayama & Cohen, 2007), we have outlined a framework to understand personality functioning that relies on these very units—beliefs, values, goals, expectations, attitudes—as the essential building blocks of an interconnected activation network (Mendoza-Denton & Mischel, 2007). We have termed this the C-CAPS framework and have applied it here to an understanding of the relationship among race, ethnicity, and personality.

As we have reviewed, conceptualizations of race and ethnicity as social and psychological constructs overlap considerably in terms of the “active ingredients” that are culturally and intrapsychically important, and as such, we argue that race and ethnicity are co-constituted with person in the same way that culture and person have been posited to make up each other. To illustrate the C-CAPS framework, we have highlighted examples of how individual differences in attitudes, expectations, and beliefs can nevertheless be interpenetrated by race and ethnicity.

CHAPTER 29

Geographical Variation in the Big Five Personality Domains

Peter J. Rentfrow and Markus Jokela

Growing evidence in personality psychology strongly suggests that personality traits are geographically clustered. Research in geographical psychology seeks to understand this phenomenon by investigating the spatial organization of psychological phenomena and how individual characteristics, social entities, and physical features of the environment contribute to their organization. Researchers working in this area have set out to (1) map the distribution of personality within and between various countries, (2) understand the causes behind geographical differences, and (3) evaluate the consequences of such geographical variation for important micro- and macro-level outcomes. Large-scale studies suggest that the personality differences between geographical regions are robust. Studies at individual and aggregate levels of analysis suggest that social influence, ecological influence, and selective migration contribute to the spatial organization of personality traits. Studies of national and regional personality indicate that the personality characteristics of regions are linked to important political, economic, social, and health indicators. Findings from multilevel studies suggest that individual differences in personality interact with features of the environment to influence psychological development and health. The implications of geographical comparisons for cultural research are discussed.

Where we live matters. The neighborhoods, cities, states, and countries in which we live can have significant consequences for many aspects of our

lives—from health, well-being, and longevity to education, career aspirations, and politics. We know this not just from personal experience but also from empirical research in geography, epidemiology, economics, and political science. Social psychologists have demonstrated that the environment plays a vital role in shaping many psychological and behavioral processes. However, social psychologists typically restrict conceptualizations of the environment to proximal factors (e.g., situations, significant others) as opposed to distal factors (e.g., neighborhoods, cities), so our understanding of the impact that place has on cognitive, emotional, and behavioral processes remains limited.

Recent research in *geographical psychology* seeks to redress this limitation by promoting a broader conceptualization of the environment that considers multiple levels of geographical analysis. A central aim of this emerging research area is to map the spatial distribution of psychological phenomena, identify the key mechanisms responsible for their geographical variation, and understand how geographical variation relates to individual- and macro-level processes. There is much in common between geographical psychology and cross-cultural psychology, as both are concerned with connections between psychological phenomena and the broader environment. However, a key difference is that research in cross-cultural psychology typically focuses on connections between psychological phenomena and cultural symbols, practices, and norms, with little attention given to the spatial nature of those connections (Oishi & Graham, 2010; Rozin, 2003), whereas studies in geographical psychology seek to discover and understand the spatial organization of psychological phenomena and how that organization relates to individual behavior and the macroenvironment (Rentfrow et al., 2013).

In this chapter, we provide an overview of research in geographical psychology, with a focus on research concerned with geographical variation in personality. We begin by offering a brief history of research concerned with geographical variation in personality. We then review evidence documenting geographical variation in personality traits, then discuss research on the mechanisms responsible for that variation. We next examine the links between geographical variation in personality and both individual and macro-level processes. We conclude by discussing the challenges and future directions for research in the field.

EVIDENCE FOR GEOGRAPHICAL VARIATION IN PERSONALITY

Nearly a century ago, psychologists and anthropologists began studying the relations between people and the places in which they live. The purpose of the research was to identify the psychological characteristics that defined citizens of nations. The investigations examined a range of psychological constructs, from unconscious urges and motives to personality traits and intellect (Adorno, Frenkel-Brunswik, Levinson, & Sanford, 1950; Buchanan & Cantril, 1953; Inkeles, Hanfmann, & Beier, 1958; McClelland, 1961; Rivers et al., 1901), and relied on a variety of methodologies, from ethnographies and participant observations to surveys and aptitude tests. For example, in the reports to the Cambridge Anthropological Expedition to Torres Straits, New Guinea, and Borneo, tests of perceptual and reasoning ability were administered to indigenous peoples. Results from the tests suggested that perceptual capacities of the local peoples were not significantly different from those of Europeans (Rivers et al., 1901). Another example is McClelland's (1961) study of national differences in achievement motivation using popular children's stories. Consistent with the theory, economic innovation and gross domestic product (GDP) were greater in nations where children's stories featured themes of goal pursuit and attainment.

Many of the results published from these early investigations were thought provoking, because they identified similarities between people in different nations and raised important questions about the possible impact that psychological variables might have on large-scale social processes, from economic prosperity to social conformity. Indeed, several of the studies conducted in the mid-20th century aimed to explain the anti-Semitism displayed before and during World War II. The findings generated by this rapidly expanding field spawned several theories about the nature of national differences in personality, as well prejudice and discrimination (e.g., Adorno et al., 1950; Lewin, 1936; Peabody, 1985).

However, despite the many interesting findings and theories generated by research on national differences, critics pointed out that the field relied largely on unreliable methods and poorly defined constructs. Consequently, it was not possible to develop a coherent unifying framework to study, much less understand, the nature of national differences in personality.

Additionally, many of the conclusions drawn from the research were ethnocentric. Thus, despite its initial impact and promise, research on national personality differences gradually faded away in the 1960s (Duijker & Frijda, 1960; Inkeles & Levinson, 1969; LeVine, 2001).

By the early 1990s, widespread consensus began to emerge among personality psychologists around an empirical framework for classifying and measuring personality traits. Factor analyses of trait ratings made by hundreds of thousands of participants provided evidence for the existence of five broad personality dimensions that can be reliably measured and used to predict behavior in multiple situations (e.g., Goldberg, 1992; John & Srivastava, 1999; McCrae & Costa, 1999). These so called “Big Five” personality dimensions spell the acronym OCEAN: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism (John, Naumann, & Soto, 2008). Openness reflects individual differences in creativity, imagination, and curiosity; Conscientiousness reflects individual differences in responsibility, discipline, and organization; Extraversion reflects individual differences in sociability, enthusiasm, and assertiveness; Agreeableness reflects individual differences in friendliness, warmth, and empathy; and Neuroticism reflects individual differences in anxiety, depression, and stress.

Numerous studies concerned with personality expression have shown that individual differences in the Big Five traits are tied to a wide range of cognitive, affective, and behavioral processes. For example, studies concerned with individual differences in preferences indicate that personality is linked to preferences for clothing, music, film, and books (Rentfrow, Goldberg, & Zilca, 2011), as well as the ways in which people decorate their homes, offices, and websites (Gosling, Ko, Mannarelli, & Morris, 2002; Vazire & Gosling, 2004). The effects of personality are not restricted to just ordinary aspects of daily life. Indeed, there is mounting evidence that individual differences in personality are associated with a range of consequential outcomes, from occupational success, morbidity, and academic achievement (Hampson, 2012; Nofle & Robins, 2007; Roberts, Kuncel, Shiner, Caspi, & Goldberg, 2007), to political orientation, religiosity, and relationship satisfaction (Ozer & Benet-Martínez, 2006).

Contemporary Research on National Differences in Personality

The evidence that the Big Five personality traits provide a robust framework for conceptualizing personality and that they have predictive relations to a range of important outcomes has led to renewed interest in geographical variation in personality. Unlike earlier efforts to identify the psychological characteristics that define citizens of nations, we now have a consensually shared and empirically based model for conceptualizing and measuring individual differences in personality across countries.

Broadly speaking, contemporary research concerned with national differences conceptualizes personality as something distinct from culture, as opposed to a product of culture (Benet-Martínez & Oishi, 2008). A core assumption within this field is that personality is biologically based and relatively stable over time, but that ecology and culture can, to varying degrees, influence the expression of personality (Hofstede & McCrae, 2004; Triandis & Suh, 2002). In other words, the opportunities and expectations within a given society interact with personality traits to shape people's preferences, habits, and skills. To that end, most studies seek to identify similarities and differences in the structure, levels, and expression of personality.

If it is indeed the case that the Big Five traits have a biological basis, it is crucial to determine whether the five factors provide a valid framework for conceptualizing and measuring personality traits for people around the world. Two approaches have been used to examine the structure of personality. The imposed etic approach involves translating Anglo-based measures of the Big Five traits into different languages, then administering the translated measures to people in different countries. The emic approach involves developing personality measures from trait descriptors from indigenous languages, then administering the measures to residents. The results from these approaches have yielded slightly different results. Studies relying on the etic approach have recovered the same Big Five trait dimensions in several countries and languages (e.g., McCrae & Costa, 1997). However, studies relying on an emic or combined etic–emic approach suggest that variants of the Big Five are recovered in many different countries and languages, with clear and consistent evidence for broad

variants of Extraversion, Agreeableness, and Conscientiousness, evidence for basic aspects of Neuroticism (i.e., anxiety, worry), but inconsistent evidence for Openness (De Raad et al., 2010; Saucier & Goldberg, 2001). Taken together, results from studies on the structure of personality strongly suggest that the Big Five provide a robust and useful framework for conceptualizing and measuring individual differences in personality for people around the world.

The evidence supporting the applicability of the Big Five in different nations allows comparison of levels of personality between them. Investigations comparing levels of the Big Five personality traits usually aggregate personality scores among residents within each nation to produce nation-level means for each trait. Comparisons of nation-level mean personality scores have revealed systematic variability in each of the Big Five traits (Allik & McCrae, 2004; McCrae, 2001; McCrae, Terracciano, & 79 Members of the Personality Profiles of Cultures Project, 2005; Schmitt, Allik, McCrae, & Benet-Martínez, 2007). For example, results from multiple investigations suggest that residents of Asian cultures score low in Extraversion; residents of Central and South American cultures score high in Openness; and residents of Southern and Eastern Europe score high in Neuroticism. Furthermore, analyses of the personality profiles of neighboring nations indicates that levels of personality are spatially clustered. Specifically, geographically close nations appear to share more psychological characteristics compared to distant nations (e.g., Allik & McCrae, 2004; McCrae et al., 2005).

However, there is also work suggesting that aggregate self-reported personality scores at the level of nations lack predictive validity. Specifically, work by Heine and colleagues suggests that self-reports of Conscientiousness tend to show relationships with macro-level variables that are the opposite of what is observed at the individual level. One explanation for this is that when individuals complete self-report measures, they compare themselves against implicit standards from their culture, not against some absolute standard (Heine, Buchtel, & Norenzayan, 2008; but see Oishi & Roth, 2009). Thus, differences between cultures may arise because people from different cultures use different standards to judge themselves. This reference group effect can make it difficult to interpret cross-national comparisons and yields results that are hard to interpret. The

reference group effect is less of a concern for comparisons within nations, because respondents likely share the same implicit cultural standards and referents (Heine et al., 2008).

Another important objective of research on national personality differences is to determine whether personality differences relate to important macro-level outcome variables. Analyses of the correlates of national personality scores have revealed associations between national levels of Neuroticism, for example, and rates of cancer, smoking, obesity, and life expectancy (McCrae & Terracciano, 2008), which suggests that the prevalence of anxious and depressed individuals is linked to disease rates and health behavior at a national level. Additionally, national levels of Openness have been linked to GDP, life expectancy, and egalitarianism (McCrae et al., 2005; McCrae & Terracciano, 2008). Such results are useful because they inform our understanding of the possible causes and consequences of national differences in personality.

Another interesting question is how measured national personality differences relate to national stereotypes, that is, how citizens of a nation are perceived by other nations. English people are often considered to be polite but uptight, Germans are thought to be industrious, and many think Greeks are carefree or even lazy, and so on. National stereotypes can be reliably measured across nations, which demonstrates that people hold systematic views of other nations' personalities (McCrae & Terracciano, 2006). However, many of these shared national stereotypes do not converge with national aggregates of self-reported personality (Terracciano et al., 2005; McCrae & Terracciano, 2006). Thus, the empirical study of national personality differences appears to undermine the validity of national stereotypes. However, there is some evidence that national stereotypes have some predictive validity. For example, national stereotypes of Conscientiousness are associated with variables that are conceptually linked to the trait, such as economic output and life expectancy (Heine et al., 2008; Oishi & Roth, 2009).

In summary, studies of national variation in personality have contributed greatly to our understanding of personality and the various cultural factors that contribute to its structure and expression. The Big Five framework provides a robust and valid model for conceptualizing personality not only within English-speaking nations but also in many other

parts of the world. Consequently, it is possible to make meaningful comparisons of the levels of personality traits across nations, which can inform our understanding of how people in different parts of the world compare on the same psychological characteristics. Moreover, the evidence linking national levels of personality to important macro-indicators reveals some of the ways in which personality at a societal level might be expressed and/or influenced by broad social, political, and economic forces. However, as important and encouraging as the research in this area is, it provides an incomplete representation of geographical variation, because regions within nations no doubt vary in many important ways.

Geographical Variation within Nations

While most research on geographical differences in personality has focused on national differences, very little attention has been given to regional differences within nations. The focus on national differences is perhaps understandable given that a central issue in the field is to identify a universal structure of personality. Thus, studies concerned with personality structure in different countries and languages are an effective approach for tackling that issue. Another objective of personality psychology is to understand behavior. Countless events throughout history have revealed differences in the values, norms, and behaviors of people around the world, so naturally personality researchers have sought to determine the extent to which national differences in important outcomes are linked to personality traits. It may therefore come as little surprise that, until recently, there has been little interest in regional variation in personality. Studies of regional personality differences within nations have methodological advantages over nation-level studies, as people within the same country share the same national culture, history, and language. Therefore, regional comparisons of personality are less obviously susceptible to cultural and language biases.

The first known study of regional personality differences aimed to identify personality differences across U.S. regions in terms of Cattell's 16 personality factors (16PF; Cattell, Eber, & Tatsuoka, 1970). Krug and Kulhavy (1973) used data from over 6,000 U.S. residents who participated in the national standardization of Cattell's 16PF model. Participants were from

36 different states, but covered all nine of the U.S. Census's multistate regional divisions, which was the geographical level investigated. Their objective was to compare residents of the different regions on each of the personality factors. The results indicated that residents of the Northeast, Midwest, and West Coast scored higher in "creative productivity" (which reflects high Openness in the Big Five model) compared to people from the Southeast, Southwest, and Mountain regions; residents from the Mountain and Southwest regions scored higher in "isolation" (which in Big Five terms would reflect low Extraversion) compared to respondents from the Midwest; and that male residents of the Mountain and Southwest regions were high in "emotional stability" compared to men in the West Coast, Northeast, and Midwest. The results from Krug and Kulhavy's investigation provided the first evidence for personality differences within a country, but the framework used for conceptualizing personality was tenuous at best, which limits the generalizability of the findings.

Nearly 30 years after Krug and Kulhavy's (1973) research, Plaut, Markus, and Lachman (2002) investigated regional variation in personality, measured in terms of the Big Five personality domains (Lachman & Weaver, 1997). As part of the Midlife in the United States (MIDUS) study of health and well-being, the researchers used a large, nationally representative sample of middle-aged adults from across the United States, who completed a brief personality measure. Even though the data were collected nearly three decades after Krug and Kulhavy's (1973) study and relied on a very different personality measure, the results were generally consistent. Specifically, the results show high levels of Neuroticism in the Mid-Atlantic and South-Atlantic regions, and high levels of Openness in the New England, Mid-Atlantic, and Pacific regions. Although Plaut and colleagues' (2002) primary interest was in identifying regionally distinct sociocultural environments, their findings offer additional evidence for regional personality differences.

The previous studies on regional personality differences are important, because they reveal converging evidence for geographical variation in personality across large, multistate regions. In an effort to determine whether there is variation at a more granular level of analysis, Rentfrow, Gosling, and Potter (2008) examined geographical variation in personality at the level of states. Specifically, they used data from the Gosling-Potter

Internet Personality Project (www.outofservice.com), where millions of people from around the world have completed the Big Five Inventory (BFI; John & Srivastava, 1999), a well-established measure of the Big Five domains. Using data from U.S. residents who reported the state they lived in at the time of completing the survey, Rentfrow and colleagues (2008) computed mean state-level personality scores and observed geographical patterns that were consistent with those reported previously. As can be seen in [Figure 29.1](#), the results showed that residents of Mid-Atlantic states down through the Midwest and Deep South were higher in Neuroticism compared to other states, and residents in New England, Mid-Atlantic, and West Coast states were higher in Openness compared to states in the U.S. Heartland.

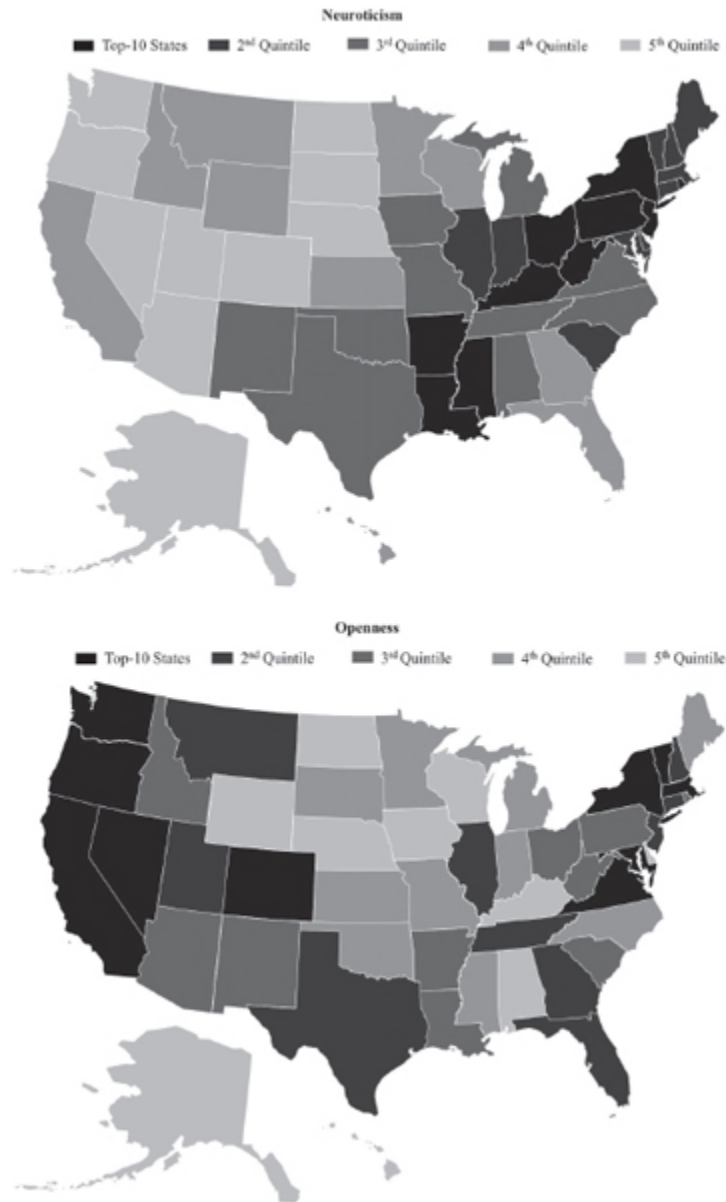

FIGURE 29.1. Regional differences in Neuroticism and Openness across the United States.

Rentfrow et al.'s (2008) findings provide further support for regional personality variation, at least within the United States, but the results were based solely on one sample of self-selected Internet users. To determine whether the results were reliable, Rentfrow et al. (2013) gathered additional state-level personality data from five independent samples that used multiple methods and Big Five instruments for assessing personality. Four of the samples were self-selected participants who volunteered to participate in online studies of personality or musical preferences, and the fifth sample was

a nationally stratified sample of registered voters who took part in the 2008 Cooperative Campaign Analysis Project (CCAP). By comparing state-level personality scores derived from each sample, the researchers were able to evaluate convergence between the samples to evaluate the reliability of the state-level scores. The results revealed convergence for all five personality domains. In a further investigation of the reliability of state-level personality scores, Elleman, Condon, Russin, and Revelle (2018), extended Rentfrow et al.'s (2013) analyses with data from two additional samples. Elleman's results revealed more converging patterns and provide compelling evidence for personality variation across the United States.

The evidence for statewide personality differences appears compelling, but like nations, many states are diverse and large, in terms of both area and population. As a consequence, it is impossible to know how much regional variance in personality exists within states. An investigation by Bleidorn et al. (2016) shed some light on this issue by examining regional variation in personality across 860 cities in the United States. The results revealed how cities compared on each of the Big Five traits. For example, levels of Openness were highest in large metropolitan cities, including Los Angeles, New York City, San Francisco, Cambridge, Massachusetts, and Miami, Florida, and lowest in small rural towns in the South and Midwest, including Andalusia, Alabama, Vidalia, Georgia, Shippensburg, Pennsylvania, and Andover, Maine. More generally, the analyses also revealed considerable regional variation in personality within states. For instance, cities within Texas ranged considerably in Openness, with five cities ranking in the top 10% of Openness and three ranking in the bottom 10%.

Although most of the research concerned with regional personality variation has been conducted in the United States, there is evidence that personality varies within regions of other countries. For example, Rentfrow, Jokela, and Lamb (2015) examined regional personality differences across the 380 Local Authority Districts (LADs) across England, Wales, and Scotland. The LAD unit of analysis is smaller physically and has fewer residents than do U.S. states, which allows for a more fine-grained analysis of geographical variation. As in the United States, the results revealed variation in personality across LADs. For instance, as can be seen in [Figure](#)

29.2, the patterns revealed high levels of Agreeableness throughout most of Scotland, Northern England, the East Midlands, and Southwest England.

FIGURE 29.2. Regional differences in Agreeableness across the United Kingdom.

Moving to an even smaller geographical scale, there is evidence to suggest that personality might vary systematically within large urban areas. Specifically, using a subsample of London residents from the data reported in Rentfrow et al. (2015), Jokela, Bleidorn, Lamb, Gosling, and Rentfrow (2015) examined the distribution of personality across 216 London postal districts. As can be seen in [Figure 29.3](#), the results from this investigation

revealed distinct geographical patterns, with high levels of Openness in the central districts of London and gradually lower levels in the outer districts.

FIGURE 29.3. Regional differences in Openness across London.

A few general conclusions can be derived from the burgeoning research on geographical variation in personality within nations. First, the evidence suggests that regional variation in the Big Five domains is robust, at least within the United States. Additional data are needed to evaluate the reliability of variation in other countries. Second, personality trait levels appear to be concentrated in neighboring areas, with close areas showing more similar levels compared to distant areas. Third, regional personality variation is not restricted to large countries with high residential mobility (e.g., the United States), but also emerges in smaller nations with lower levels of mobility (e.g., the United Kingdom). Fourth, analyses of U.S. cities,

British local authorities, and a major metropolitan city suggest that new patterns of personality variation appear when descending from larger to smaller geographic scale, and that some of the variation observed at broader levels of analysis is probably driven by urban and rural differences, as well as population diversity. Taken together, the evidence for regional personality differences appears compelling, but an important question about the differences remains: What are the mechanisms responsible for geographical variation in personality?

WHAT ARE THE CAUSES OF GEOGRAPHICAL DIFFERENCES IN PERSONALITY?

The forces that shape geographical variation in personality most certainly occur over extended periods of time. Therefore, the evidence necessary to empirically evaluate the factors that contribute to such variation requires longitudinal data from large samples of participants in nations with relatively high levels of residential mobility. Not surprisingly, there are not yet data available to directly examine the mechanisms that drive geographical variation. However, in the absence of such data, we may draw from theory and research in the social sciences to develop hypotheses about the mechanisms that are likely responsible. According to the literature, at least three mechanisms may contribute to geographical variation: social influence, ecological influence, and selective migration (Heine & Buchtel, 2009; Hofstede & McCrae, 2004; Jokela, 2009; Jokela, Elovainio, Kivimäki, & Keltikangas-Järvinen, 2008; Kitayama, Ishii, Imada, Takemura, & Ramaswamy, 2006; Rentfrow et al., 2008).

The hypothesis that *social influence* contributes to geographical variation in personality is based on decades of research, which indicates that features of the social environment influence how people think, feel, and behave. Although most studies of social influence focus on attitudes, beliefs, and emotional states, research in cultural psychology offers some evidence that socialization creates opportunities and reward structures that encourage certain personality traits, which could affect the prevalence of those traits in a given area (e.g., Benet-Martínez & Oishi, 2008; Bond et al., 2012; Hofstede, 2001; Hofstede & McCrae, 2004; Triandis & Suh, 2002).

There is considerable evidence on how the social environment may impact individuals in a variety of ways (e.g., Bond et al., 2012; Christakis & Fowler, 2008; Kramer, Guillory, & Hancock, 2014). One example of large-scale social influence may be seen in advertisements used in online social media sites. For example, Bond et al. (2012) examined the impact of informational versus social messages on voter behavior in a large sample of Facebook users and found that users were much more likely to vote in the U.S. Congressional Election if they saw friends who had voted compared to users who did not. Another example of the impact of the social environment on people's behavior may be found in the epidemiology literature. Specifically, for several decades, rates of stroke and heart disease have been disproportionately high in the southeastern areas of the United States, a region dubbed the "Stroke Belt." In a longitudinal investigation aimed at determining whether people who moved away from the "Stroke Belt" experienced improvements in health compared to people who remained, Glymour, Avendaño, and Berkman (2007), controlling for demographic and socioeconomic characteristics, found that the health risks associated with living in the "Stroke Belt" persisted even years after people settled in a different part of the country. The explanation is that a high-fat diet is part of Southern U.S. culture, so people raised in the region adopt unhealthy eating habits that are maintained long after people leave. Although there is no direct evidence that social influence drives geographical variation in personality, the available evidence clearly shows that various features of the social environment can impact individuals and have large-scale effects. It therefore seems reasonable to assume that social influence must contribute to geographical variation in personality and other psychological characteristics.

The second mechanism that most likely contributes to geographical variation in personality is *ecological influence*. The hypothesis is that features of the physical environment, such as temperature, precipitation, and population density, influence people's opportunities and behaviors, which could encourage certain personality traits to predominate in an area. Evidence from several studies, mainly from a cultural-psychological perspective, provide compelling support for this hypothesis by suggesting that specific features of the natural and built environment have consequential outcomes for personality.

Studies on ecological influence have focused on a range of environmental features, from pathogen prevalence and climate to urban crowding and green space (Anderson, 1989; Cutrona, Wallace, & Wesner, 2006; Fincher, Thornhill, Murray, & Schaller, 2008; Schaller, 2006; Schaller & Duncan, 2007; Schaller & Murray, 2008; Van de Vliert, 2013; White, Alcock, Wheeler, & Depledge, 2013). One example of ecological influence comes from research concerned with the impact of subsistence strategies on personality. Specifically, Talhelm et al. (2014; Talhelm & Oishi, [Chapter 4](#), this volume) found that people from Southern China, where subsistence depends on rice farming, were more perceptually interdependent and holistic thinking compared to people from Northern China, where subsistence depends on wheat farming. The explanation is that rice farming requires cooperation and therefore encourages more interdependence between people compared to wheat farming, which requires less cooperation. Research by Schaller and colleagues provide another example of ecological influence (Schaller, 2006; Schaller & Duncan, 2007; Schaller & Murray, 2008). That research strongly suggests that nations with historically high pathogen prevalence levels are comparatively high in Conscientiousness and low in Extraversion and Openness. The explanation for this association is that psychological traits that encouraged caution and discouraged social contact and exploration were reinforced because they limited exposure to disease-causing pathogens.

Social and ecological influences emphasize the effect the environment has on individuals, whereas *selective migration* emphasizes the role that individuals play in choosing their environments. The hypothesis draws on interactionist theories of personality and postulates that individuals seek and create environments that satisfy their needs. For example, when choosing to relocate, people must consider what they can afford, how large of a space they want, how far they are willing to commute to work, whether the area is sufficiently safe, whether it is important to live near family, and so forth. There is variance in what people decide for each of these issues, and there is evidence that personality accounts for some of that variance. For instance, Agreeableness is related to desires to move to places regarded as friendly, Neuroticism is related to desires to move to safe and friendly areas, and Openness is related to desires to move for professional and educational opportunities (Jokela, 2014a). Personality also appears to be associated with

preferences for particular types of environments. Results from small- and large-scale studies suggest that preferences for mountainous environments are greater for people low in Extraversion, because such environments foster feelings of solitude and reflection, and that preferences for beaches are greater among people high in Extraversion, because such environments encourage affiliation and social interaction. The explanation for these findings is that individuals are drawn to environments that satisfy their psychological needs (Oishi, Talhelm, & Lee, 2015). There is also evidence that people who have settled in frontier regions, which are rugged, undeveloped, and have limited social order, possess a greater sense of freedom, independence, autonomy, and novelty seeking compared to residents of more developed regions (Kitayama et al., 2006).

Evidence from longitudinal studies indicates that certain personality traits are associated with selective migration. The results suggest that people high in Openness and Extraversion are more likely to move across regions to urban and cosmopolitan areas compared to people low on those traits (Camperio Ciani et al., 2007; Jokela, 2009, 2014b; Jokela et al., 2008). The explanation for the findings is that large cities are vibrant and culturally diverse, which creates an atmosphere that is appealing to people high in Openness and Extraversion (Jokela et al., 2008). In addition, a few studies suggest that Agreeableness, which is associated with warmth, generosity, and cooperation, is related to settling near extended family and not moving away from one's hometown (Boneva et al., 1998; Jokela, 2009). There is also evidence that individual differences in political values are linked to migration patterns, such that people are more likely to move to areas where they believe residents are likely to share their values (Motyl, Iyer, Oishi, Trawalter, & Nosek, 2014). Taken together, there is considerable evidence that personality traits and other psychological characteristics are linked to people's decisions about whether to move and where to settle. Therefore, it seems reasonable that such sorting on a large scale contributes to geographical variation in personality.

In summary, social influence, ecological influence, and selective migration are three mechanisms hypothesized to contribute to geographical variation in personality. A considerable amount of indirect evidence strongly suggests that each mechanism may have large-scale effects, which makes it reasonable to accept these mechanisms as likely factors. The

mechanisms are likely to contribute to geographical variation both across and within nations, but the relative impact each has at different geographical levels of analysis is as yet unclear.

WHAT ARE THE CONSEQUENCES OF GEOGRAPHICAL DIFFERENCES IN PERSONALITY AT A MACRO LEVEL?

The work reviewed thus far strongly suggests that there is geographical variation in personality between and within nations, and that social influence, ecological influence, and selective migration are three mechanisms that contribute to that variation. An important component of research in this area seeks to determine whether geographical personality differences are linked to consequential outcomes. After all, research in political science, economics, sociology, and epidemiology consistently reveal geographical variation on several macroindicators, from voting behavior and income inequality to crime and mortality. All of these indicators are the result of individual-level behaviors, and a considerable amount of research has established robust connections between individual differences in personality and political orientation, education, career preferences, prosocial behavior, and physical health. It therefore seems reasonable to expect personality to account for a portion of the variance in geographical differences in political, economic, and health indicators.

An advantage of working with aggregate personality data for nations and regions is that, in many cases, secondary data are available for a range of indicators. Consequently, analyses can be carried out to investigate how region-level personality scores relate to a range of macro-level indicators. Such analyses are useful, because they can indicate the degree to which psychological processes generalize across multiple levels of analysis and cultures. Furthermore, the results have the potential to reveal whether psychological characteristics contribute to important macro-level outcomes, such as rates of mental illness, crime, and obesity. To date, most of the research on geographical personality differences has focused on how the personality trait levels relate to political, economic, social, or health indicators.

However, when working with variables that can be measured at multiple levels of analysis (e.g., at the levels of individuals and regions), it may be tempting to assume that findings from one level also apply at another level, but the different levels are logically independent. A failure to recognize this logical disconnection can lead researchers to make incorrect inferences about individuals on the basis of aggregate-level data (i.e., the ecological fallacy; Robinson, 1950) or incorrect inferences about aggregates on the basis of individual-level data (i.e., the individualistic fallacy; Inglehart & Welzel, 2003). This logical disconnect was famously demonstrated over half a century ago in a classic study by Robinson (1950), which showed that the ecological (i.e., aggregate-level) correlation between the percentage of foreign-born state residents and the percentage of illiterate state residents was $-.53$, but that the individual-level correlation between foreign-born status and illiteracy was $.12$. In this example, the ecological fallacy would be committed if one were to assume, solely on the basis of the ecological correlation, that foreign-born residents are more literate than native-born residents. Likewise, the individualistic fallacy would be committed if one were to assume, solely on the basis of the individual correlation, that regions with large foreign-born populations have low literacy rates. Failing to recognize that aggregate and individual levels of analysis are independent can lead to erroneous conclusions. Thus, within the context of research on geographical variation in personality, it is crucial that we are mindful of cross-level independence in our interpretations and generalizations of results.

Political

Recent U.S. political elections have sparked interest in the so called “red state–blue state divide,” with pundits focusing on the social and economic differences between left-leaning and right-leaning states. However, the United States has been divided politically since it was founded, which is why there is a well-established field of research concerned with political geography. Much of the research in this area focuses on the impact of social and economic factors on political opinion and voting behavior. For example, there is evidence indicating that the level of ethnic diversity in regions plays

an important role in political values of residents (Heppen, 2003; Hero, 1998). Regions with little racial diversity have undifferentiated social structures and are concerned with community development, whereas regions with diverse populations have more complex social structures and focus on social order, and are less trusting of others (Hero, 1998; Putnam, 2007). Such research is important and informs our understanding of the factors that influence political opinion and voting patterns.

The burgeoning research in geographical psychology demonstrating regional personality differences raises the question of whether regional variation in political opinion might be linked to the psychological characteristics of residents. In fact, there is clear evidence that certain personality traits are linked to political ideology. According to Jost, Federico, and Napier (2009), ideology serves to inform individuals' beliefs about the structure and order of society, and personality traits associated with fear, compliance, and tolerance have been linked to individual differences in political values. Specifically, results from numerous studies indicating that high Conscientiousness and low Openness are linked to political conservatism in the United States.

Rentfrow, Jost, Gosling, and Potter (2009) sought to determine whether regional personality differences in the United States are linked to voting behavior. Using the state-level personality estimates reported in Rentfrow et al. (2008), the researchers examined the links between state-level personality traits and percentages of votes cast in the 1996, 2000, and 2004 U.S. Presidential elections. The results strongly suggested that states with high Openness and low Conscientiousness cast significantly more votes for Democrats, whereas states low in Openness and high in Conscientiousness supported Republicans (Rentfrow et al., 2009). To evaluate the reliability of these associations, Rentfrow et al. (2013) examined the patterns of associations between personality and political orientation using state-level personality scores from five independent samples. The forest plots shown in [Figure 29.4](#) depict the patterns of associations for each sample and clearly indicate that state-level Conscientiousness and Openness are reliably associated with political orientation in the United States.

Votes for Republicans

FIGURE 29.4. Fixed-effect meta-analysis of associations between state-level mean personality traits and proportion of votes for Republicans in the 2004 and 2008 U.S. presidential elections. Estimates are regression coefficients between standardized personality scores ($SD = 1$) and outcome assessed at state level. Within each sample, all personality traits were mutually adjusted, that is, included in the same regression model.

To evaluate the generalizability of the links between regional personality and voting behavior, Rentfrow et al. (2015) examined associations between the aggregate personality traits of political constituencies and proportions of votes cast for the Labour, Conservative, and Liberal Democrat parties in the 2005 and 2010 U.K. general elections. Consistent with the patterns observed

in the United States, the results indicated that Conscientiousness was positively related to votes for the Conservative party and negatively related to votes for the Labour party, and that Openness was positively correlated with votes for the Liberal Democrats. Moreover, these patterns of associations remained even after the researchers controlled for the economic and population characteristics of regions.

Taken together, research on the psychological correlates of regional voting trends reveals very robust associations, suggesting that, at least in the United States and the United Kingdom, the personality traits of residents contribute to collective voting behavior. These findings add further support for the importance of psychology for understanding political ideology. Moreover, as identity politics continues to rise and attract support from political fringe groups, future research in geographical psychology will be valuable for developing and testing hypotheses about the factors that contribute to local political values and possible ways to foster connections between groups.

Economic

Research in macroeconomics focuses on the spatial organization of wealth, industries, and employment. Typically, researchers focus on factors such as GDP, labor statistics, and unemployment rates to understand the structure of economies. However, growing interest in economics is focusing on the impact that “intangible factors,” such as creativity and trust, have on regional economics. For example, Florida (2002, 2008) conducted a considerable amount of research concerned with regional variation in creative innovation, with the goal of understanding why certain regions are more economically prosperous than others. The key finding to emerge is that diversity within regions fuels creative innovation and economic growth. One part of the explanation is that creative people are attracted to regions that are diverse and vibrant, because such places are stimulating. The other part of the explanation is that individuals who live in diverse regions are more likely to have regular contact with people from different cultures, ethnicities, sexual orientations, and backgrounds, which broadens individuals’ worldviews and promotes divergent thinking. As a result, diverse areas

accrue creative capital by way of selective migration and social influence, which contributes to innovation, creates jobs, and generates wealth.

In many ways, creative capital is psychological in nature, because it is based on concepts of imagination, curiosity, and tolerance, which are core aspects of Openness. It therefore seems reasonable to expect creative capital to be linked to regional variation in Openness. Consistent with this expectation, state- and city-level analyses suggests that regions high in Openness have large proportions of high-tech firms, patents, artists, entertainers, foreign-born residents, and same-sex couples (Rentfrow, 2011; Rentfrow et al., 2008). For example, regions that have large shares of creative industries (e.g., San Francisco, Cambridge, Massachusetts, Austin, Texas) also rank at the top on Openness. As a check on the robustness of the state-level findings, Rentfrow et al. (2013) analyzed in five samples the links between state-level personality and economic innovation. As can be seen in [Figure 29.5](#), Openness emerged as a positive predictor of innovation in all five samples. Overall, these findings suggest that Openness in regions promote tolerance, self-expression, and creativity, which might foster innovation and prosperity.

Innovation Index

FIGURE 29.5. Fixed-effect meta-analysis of associations between state-level mean personality traits and state's innovation index. Estimates are regression coefficients between standardized personality scores ($SD = 1$) and outcome assessed at state level. Within each sample, all personality traits were mutually adjusted, that is, included in the same regression model.

Recently, Lee (2017) examined the geography of innovation in England and Wales, and its relation to the personality traits of residents. Based on analyses of travel-to-work areas, the results indicated that Conscientiousness was most consistently associated with economic innovation. Furthermore, by using religious observance in 1851 as an instrumental variable, analyses suggested that regional Conscientiousness is a causal force behind innovation. These findings suggest that work ethic is a key driver of creative innovation and prosperity in England and Wales. In a related line of

research, Obschonka, Schmitt-Rodermund, Silbereisen, Gosling, and Potter (2013) investigated whether the prevalence of individuals with an entrepreneurial psychological profile (defined by high Openness, Conscientiousness, and Extraversion, and low Neuroticism and Agreeableness) is associated with economic prosperity in the region. Results from the United States, the United Kingdom, and Germany converged, indicating that rates of innovation were greater in regions with large proportions of people with the entrepreneurial personality profile.

“Social capital,” another intangible factor that has received considerable attention in economic geography, reflects the degree to which residents of an area feel a sense of trust and connection to their neighbors. Putnam (2000) showed that social capital is clustered in the United States, with regions in the Great Plains and Midwest showing high levels compared to the South. Furthermore, involvement in civic organizations, high voter turnout, and low crime are characteristics of places high in social capital. Social capital has a strong psychological component that emphasizes concepts of warmth, trust, and empathy, which are core aspects of Agreeableness, so it is conceivable that social capital might be associated with levels of Agreeableness in regions. In the United States, high levels of Agreeableness and Extraversion were linked to Putnam’s (2000) social capital index, as well as to high civic engagement and low crime rates (Rentfrow, 2010; Rentfrow et al., 2008). In the United Kingdom, regional variation in Agreeableness was also associated with lower crime rates and low cultural diversity (Rentfrow et al., 2015).

As research in economics continues to focus on intangible sociocultural factors that are difficult to measure directly, research in geographical psychology has the potential to address that limitation. Indeed, many of the intangible factors have characteristics that map onto well-developed psychological constructs that can be measured reliably. Thus, aggregate psychological data may provide psychometrically superior alternatives to tangible proxy indicators. Furthermore, establishing links between aggregate personality traits and economic indicators further establishes the importance of psychology for understanding the structure and behavior of large economies.

Health

One particularly rich area for research in geographical psychology concerns the links between regional personality and health. An impressive amount of work has examined the social and psychological determinants of health and well-being (Miyamoto, Yoo, & Wilken, [Chapter 12](#), this volume). Indeed, developing an understanding of regional health disparities and identifying effective methods for mitigating them are crucial for promoting public health. One especially strong thread of research has identified a connection between socioeconomic status (SES) and health, such that levels of psychological and physical well-being improve as SES increases (Adler et al., 1994; Adler, Marmot, McEwen, & Stewart, 1999; Gallo & Matthews, 2003). The effects of SES on health are not restricted to a person's SES, because the socioeconomic characteristics of the neighborhoods in which people live also appear to impact psychological and physical health (Cutrona et al., 2006; Fauth, Roth, & Brooks-Gunn, 2007). For example, studies have shown that rates of obesity and the prevalence of stress hormones are higher among people living in low SES neighborhoods, even after researchers control for family SES (Chen & Paterson, 2006).

There is compelling evidence that individual differences in personality are linked to health and life expectancy (Jokela et al., 2013; Jokela, Pulkki-Råback, Elovainio, & Kivimäki, 2014; Roberts et al., 2007). For example, Extraversion is positively associated with having large social support networks, and some evidence suggests people high in Extraversion have long life expectancies (Ozer & Benet-Martínez, 2006). There is evidence that Conscientiousness is positively related to health-promoting behaviors, such as exercising, and negatively related to health-damaging behaviors, including heavy drinking and drug use (Atherton, Robins, Rentfrow, & Lamb, 2014; Hakulinen et al., 2015; Jokela et al., 2013). And Neuroticism is associated with shorter life expectancy for men and women, and higher disease death rates. Importantly, results from meta-analyses indicated that effects of personality on mortality are comparable to the effects of SES on mortality (Jokela et al., 2013; Roberts et al., 2007).

Are regional differences in health and mortality linked to personality? Rentfrow et al. (2008) observed correlations between state-level personality and a number of health indicators. The most consistent pattern of

associations emerged for state-level Neuroticism. Specifically, states high in Neuroticism had more deaths due to all forms of cancer and heart disease, and shorter life expectancies. The links between Neuroticism and the health indicators remained even after researchers controlled for population characteristics of states. To determine whether the patterns of associations were reliable, Rentfrow et al. (2013) examined links between state-level Neuroticism in five samples and a well-being index that comprised markers of life expectancy: deaths due to cancer, stroke, and heart disease. As can be seen in [Figure 29.6](#), high Neuroticism was associated with low well-being in every sample.

Well-Being

FIGURE 29.6. Fixed-effect meta-analysis of associations between state-level mean personality traits and state's well-being index. Estimates are regression coefficients between standardized personality scores ($SD = 1$) and outcome assessed at state level. Within each sample, all personality traits were mutually adjusted, that is, included in the same regression model.

The links between regional personality and health outcomes are not restricted to the United States. Rentfrow et al. (2015) observed similar patterns of associations in the United Kingdom. District-level Neuroticism was positively related to the proportion of residents with long-term health problems, and deaths due to cancer, and heart disease, and negatively related

to life-expectancy in men and women. Furthermore, these effects remained after researchers controlled for population characteristics.

Taken together, research on the psychological correlates of regional health indicators reveals robust associations between physical health and Neuroticism. These findings add further support for the importance of psychology for understanding and promoting public health. Given the role of personality in regional health differences, it is conceivable that theory and research in personality might be useful for developing methods to promote positive health behavior.

WHAT ARE THE CONSEQUENCES OF GEOGRAPHICAL DIFFERENCES IN PERSONALITY AT THE INDIVIDUAL LEVEL?

We know from decades of research in psychology that the environment plays an important role in shaping cognitive and social development, as well as behavior. However, psychologists typically define environment in either quite narrow terms, such as the nuclear family, peer groups, or the immediate situation, or in very broad terms, such as national culture. By refining conceptualizations of the environment to include the places people live, such as neighborhoods, cities, and regions, studies of geographical differences in personality can shed new light on the ways in which psychological processes and environmental factors interact and impact individuals.

One example of how geographical psychology can inform our understanding of psychological processes comes from a line of research concerned with the impact of the environment on personality maturation. Questions about the stability of personality, and the possible role that the environment has in shaping it, have been the focus of many studies. One camp of researchers who advocate a strong genotypic position argues that personality traits are rooted in biology and are immune to environmental influences (e.g., McCrae & Costa, 2008). Another camp promotes the view that personality traits, although biologically based, can be shaped, to some degree, by the environment (e.g., Roberts, Wood, & Smith, 2005). By examining geographical differences in personality using a large age-

diversified sample, Bleidorn et al. (2013) investigated age trends in personality to determine whether the trajectories of personality development were the same across countries, as would be expected from the genotypic perspective, or different, as would be expected from the phenotypic perspective. The results revealed different age trends per country and suggested that the sociocultural characteristics of countries influenced the age trajectories. More specifically, in countries where financial independence and family formation begin comparatively early in development (late teens), developmental changes in Conscientiousness, Neuroticism, and Openness emerged earlier, too. In general, what these findings suggest is that the social and economic characteristics of an area can impact the personalities of the people who live there.

A central component of the selective migration hypothesis is that people are drawn to environments that satisfy their psychological needs. It is assumed that when people live in environments that meet their needs, they are happier and more satisfied with life. This seems to be a reasonable assumption given that individuals have reported greater satisfaction and more positive affect when in situations that “fit” with their personalities (Ickes, Snyder, & Garcia, 1997). Moreover, being in a social environment where one’s needs are met can foster feelings of belongingness and enhance self-esteem (Fulmer et al., 2010; Leary & Baumeister, 2000). But is there evidence that people really are more satisfied and confident when there is a psychological fit between their personal traits and characteristics of their environment?

Bleidorn et al. (2016) set out to address the question of whether a match between people’s personalities and the characteristics of their cities enhances self-esteem. Using a large sample with data for 860 U.S. cities, they examined whether individuals’ self-esteem was greater if their personalities resembled the characteristics of their city. The results suggested that instead of an overall fit pattern across the Big Five personality traits, Openness, Agreeableness, and Conscientiousness showed small but statistically significant fit effects on self-esteem. In other words, people experience comparatively high self-esteem when their levels of curiosity, friendliness, and self-discipline are similar to those of their neighbors.

Living in an environment that offers opportunities and amenities that complement one’s personality might also contribute to well-being. For

example, people who value spending time with their families and children might be more content living in places that support domestic life, whereas people who enjoy attending museums, art galleries, and the theater might be happier in an area rich with cultural opportunities. There is some empirical evidence to support this line of reasoning. Specifically, in their study of geographical personality differences in London, Jokela, Bleidhorn, Lamb, Gosling, and Rentfrow (2015) examined whether people are more satisfied with their lives when they live in neighborhoods that have characteristics that complement their personalities. The results indicated that that people high in Agreeableness were more satisfied with life when they lived in neighborhoods with large shares of family-occupied households, green space, and low crime. One explanation for these associations is that people high in Agreeableness place considerable importance on close relationships (Graziano, & Tobin, 2009) and are therefore happiest living in places where they can raise families safely. Another noteworthy finding was that people high in Openness were happier living in densely populated and culturally diverse neighborhoods. The explanation for this result is that people high in Openness seek stimulation and are thus satisfied living in active and vibrant places. These results indicate that not all places are liked equally by everyone and suggest that cities with a wide range of residential options increase choice and may promote greater well-being among residents.

LIMITATIONS AND FUTURE DIRECTIONS

The burgeoning field of geographical psychology is young, so there is still a lot that we do not know and many challenges to overcome. What we know so far about geographical differences in personality is limited in many ways. A crucial limitation of nearly all the research in this area is that it is based on large Internet samples of convenience. Because most studies of regional personality differences have relied on self-selected participants who, through various means, arrived at a website and volunteered to complete a brief personality assessment would seem to restrict the generalizability of the findings. Access to the Internet has proliferated through the years and is increasingly available throughout most areas of the Western World. Thus, the reliance on Internet-based methods may be less limiting for studies in

North America and parts of Western Europe. However, reliance on the Internet is likely a greater problem for research in parts of the world where Internet access is more restricted and limited primarily to mobile phones. The net result of this methodological limitation is the underrepresentation of minority groups, older populations, and individuals with limited education, and the overrepresentation of people high in Openness.

A second limitation of research on regional variation is the reliance on self-reports of the broad Big Five personality domains. Although the Big Five provide a robust and psychometrically applicable model for measuring personality, there is more to a person than these traits. Thus, we do not know whether particular facets of personality are relevant for understanding geographical personality differences. More generally, we know very little about whether other important psychological characteristics vary across regions and impact macro- or micro-level processes. A notable exception is subjective well-being, for which there is a considerable amount of evidence showing variation between nations and regions (Diener, Helliwell, & Kahneman, 2010; Diener, Oishi, & Lucas, 2015; Lawless & Lucas, 2011). There are also considerable data at the country level that have examined cross-national differences in psychological values, gender roles, and religiosity (e.g., Alesina, Giuliano, & Nunn, 2013; Powers et al., 2003; Welzel, Inglehart, & Kligemann, 2003). But it is less clear how these constructs vary across regions within nations. Exploring geographical variation in these and other constructs will not only yield interesting information about how they are distributed across regions, but more importantly, it might illuminate new ways of thinking about the constructs and how they relate to broader environmental factors.

Although the use of self-report methods for exploring geographical differences is practical and efficient, especially when large samples are needed, data from laboratory-based methods would be useful for determining whether experimental effects generalize across regions. Other methods, such as using peer-reports of a target person's personality, could be used to mitigate biases of self-report measures (McCrae & Terracciano, 2006). With the rise of data archiving services and platforms that facilitate collaboration among researchers at different institutions, such as the Open Science Framework, experimental data from laboratories located in different regions can be collected quite easily. Such resources make it possible to

conduct large collaborative projects, with the aim of mapping effect sizes across regions. Such multisite endeavors have the potential to shed new light on important psychological processes and at the same time provide a basis for developing and testing hypotheses about the ways in which personal and environmental factors interact.

A third limitation of research in this area is the reliance on cross-sectional data. Although there is evidence that state-level personality scores have been stable from 1999 to 2015 (Elleman et al., 2018), the data are based on single assessments of participants at one point in time. Longitudinal individual-level data that assess participants over time and track their location of residence will be essential for evaluating the degree to which personality traits influence migration decisions and whether personality traits change in response to features of the social and physical environment (in this volume, see Mesoudi, [Chapter 5](#); Mesquita, De Leersnyder, & Jasini, [Chapter 19](#); Morris, Fincher, & Savani, [Chapter 18](#)). For example, there is evidence from cross-sectional research suggesting that the younger people are when they move to a new culture, the more they identify with and share the values of that culture later in life (Cheung, Chudek, & Heine, 2011). Presumably, there is a critical developmental period when individuals are more likely to integrate the values of the host culture. However, more recent work with larger and more diverse samples suggests that the process is more complex (Chudek, Cheung, & Heine, 2015). Nonetheless, the point is that longitudinal research designs would yield valuable information about the ways in which psychological and environmental factors interact.

Investigating relations between psychological processes and residential status over time also has the potential to reveal valuable information about the possible effect of the environment on psychological processes. For example, two longitudinal studies in Australia and the United Kingdom (Jokela, 2014b; 2015) showed that people's health changed very little when they moved between more and less deprived neighborhoods, which suggests that economic deprivation within neighborhoods may not cause poor individual health. However, research from the Moving to Opportunity Project suggests that children who moved from a poor area to a less deprived area enjoyed economic and professional benefits later in life (Chetty, Hendren, & Katz, 2016).

Within the context of personality research, longitudinal studies would be useful for determining whether the forces that drive geographical personality differences influence all traits to the same extent. It seems reasonable to expect social and ecological influence to contribute more to national personality differences than selective migration, although selective migration may be more influential in relatively young countries (like the United States). It is also unclear whether the mechanisms influence the distributions of all traits equally, or if some mechanisms play more prominent roles in shaping the distributions of specific traits more than others. Drawing on evidence that Openness tends to be high in urban areas, and findings suggesting that individuals high in Openness are attracted to cosmopolitan cities, it is conceivable that regional variation in Openness might be driven by selective migration more than social or ecological influence.

Maps of geographic variation in Neuroticism show rather large regional clusters, suggesting that levels of the trait are not driven by urban–rural differences. Research on emotional contagion (e.g., Fowler & Christakis, 2008) suggest that social influence might play an important role in shaping regional levels of Neuroticism. To the extent that individuals’ moods are influenced by the people they encounter, it is conceivable that contact with anxious and depressed people might increase feelings of negative affect and yield high levels of Neuroticism. Nonetheless, longitudinal studies will inform our understanding of the nature of such geographical differences.

CONCLUSION

Research in geographical psychology offers a rich new direction for developing and testing hypotheses about the ways in which individuals interact with the environment. Progress in personality psychology over the past two decades has helped to overcome many of the limitations that plagued early investigations of national and regional personality differences. We now have empirically based models and psychometrically valid methods for conceptualizing and measuring individual and geographical differences in personality. The research conducted thus far offers compelling evidence that there are robust and meaningful personality differences across nations

and regions within nations. The forces behind these differences appear to be a combination of environmental and personal factors. Geographical differences in personality have consequential outcomes at both the macro and micro levels of analysis. Although this area of research is still in its early days, the discoveries made so far are promising and have the potential to broaden our understanding of human behavior, the broad forces that shape it, and the ways in which it impacts the world.

CHAPTER 30

Cultures of Honor

**Ayse K. Uskul, Susan E. Cross, Ceren Günsoy,
and Pelin Gul**

Cultures of honor developed in contexts in which a person's livelihood was easily stolen (e.g., a herd of animals) and the rule of law was weak. In such contexts, men were required to develop a reputation for toughness and willingness to retaliate quickly and aggressively when threatened, so that others would not consider stealing their property. Consequently, cultures of honor have developed ideologies, norms, and practices that reinforce the importance of maintaining social respect through aggressive means, if necessary. In this chapter, we first briefly review the initial work by anthropologists, sociologists, and historians that describes cultures of honor in the Mediterranean region and Southern United States. This early work formed the foundation of research by Nisbett, Cohen, and their colleagues, who carefully articulated a psychological theory of how concerns for honor may explain higher rates of aggression and violence in Southern compared to Northern United States. We then summarize research on components of honor, behavioral and psychological consequences of honor, and socialization practices that maintain cultures of honor. We finish by discussing possible future directions and methodological considerations in research on cultures of honor. This research has extended the scope of cultural psychology by going beyond the more common East–West comparisons; it has the potential to help explain behavior of groups that have not been widely studied by social psychologists.

The slogan “Don’t mess with Texas” is plastered on billboards, road signs, and souvenirs from this U.S. state. It was originally designed as part of an antilittering campaign, but it quickly caught on as a statement of Texas identity and braggadocio. In this context, to “mess with” someone means to

taunt, tease, or threaten them in some way, and Texans are proud of their heritage of standing up to such threats (Fehrenbach, 2000).

Texas is one example of a culture of honor, where defense of one's reputation by violence, if necessary, is a key cultural concern. The construct of cultures of honor has emerged in the past two decades as an important theoretical perspective that explains cultural variation in attitudes, behavior, and practices. This topic was brought to the attention of the field by the pioneering work of Nisbett and Cohen (e.g., Nisbett, 1993; Nisbett & Cohen, 1996). They focused on how the Southern and Western regions of the United States may be understood in terms of culture of honor formulations first developed by anthropologists studying Mediterranean communities. Since their initial research in the 1990s, many other researchers have effectively applied this conceptualization to understand cultural influences on behavior in regions that are characterized by a culture of honor. In this chapter, we first briefly review the research that led to Nisbett and Cohen's (1996) articulation of the culture of honor theory in the context of social psychology and the research that has ensued.

HISTORICAL AND ANTHROPOLOGICAL FOUNDATIONS

Three streams of scholarship laid the foundation for Nisbett and Cohen's ground-breaking work on the Southern culture of honor in the United States. The first stream came from anthropologists working in Greece, Spain, and other Mediterranean contexts, who described honor as a core concern in the region. One of the first anthropologists to write about honor, Pitt-Rivers (1965) described it this way: "Honor is the value of a person in his own eyes, but also in the eyes of his society" (p. 21). This definition includes the individual's self-esteem and social image (or reputation)—how the individual evaluates him- or herself, and how others evaluate the individual. The foundations or sources of these evaluations are unmentioned in this definition, but they include the individual's adherence to a particular honor or moral code (the behaviors expected of a person in that cultural context), as well as the person's roles or status in the community (Campbell, 1964; Gilmore, 1987; Peristiany, 1965). Honor and respect are easily lost in these

cultural contexts and, once lost, difficult to recover (Stewart, 1994). Consequently, people engage in a variety of behaviors meant to earn or maintain others' respect (e.g., living by the local honor code) or to defend their reputation from affront (Peristiany, 1965). The importance of honor in these cultural contexts is expressed in proverbs such as "Give your life; take honor in return" (Circassian) and "Honor before bread" (Arabic).

The second stream of scholarship started soon after the publication of the work by Pitt-Rivers (1965) and Peristiany (1965) describing the culture of honor in the Mediterranean, when Edgerton (1971) and Goldschmidt (1965) published their work on culture and ecology. They found that cultural traditions and means of subsistence (farming vs. herding) both were associated with the traits, attitudes, and behaviors of members of four East African tribes. In particular, although members of individual tribes were more similar to each other than to members of other tribes, there were consistent differences between herders and farmers in each of the tribes. Compared to the farmers, herders were more independent, self-reliant, aggressive, brave, and willing to withstand hardship due to the demands of caring for willful animals, the need to find pasture and water, and constant alertness to threats to the herd. In contrast, farmers were more emotionally constrained and cooperative with others, because their livelihood did not require constant vigilance and decision making (Edgerton, 1971; Goldschmidt, 1965; see also Bolton et al., 1976).

The third stream of scholarship that shaped Nisbett and Cohen's culture of honor hypothesis was a body of historical and sociological research that focused on the cultural, psychological, and sociological characteristics that differentiated the U.S. South from other regions. Among other differences, the U.S. South was shown to be more violent than the North and Midwest regions of the United States (Gastil, 1971, 1989; Hackney, 1969). Explanations for this difference have pointed to the history of slavery (de Tocqueville, 1835/1969), higher levels of poverty and economic inequality in the South (Loftin & Hill, 1974), and hotter temperatures (Anderson, 1989). Some historians, however, argued that this difference could be a function of the settlement of the region by Scots, Welsh, and Irish. The Scots-Irish settlers brought with them a legacy of open-range herding and with it an attitude that men must respond aggressively to affronts (McWhiney, 1988; Fischer, 1989; Wyatt-Brown, 1982, 1986; see Brown & Osterman, 2012, for a

useful summary). When men were the victims of affronts, threats, or theft, legal means of recourse were often unavailable; thus, they were expected to take matters into their own hands and duel or fight it out (McWhiney, 1988). In contrast, the Anglo-Saxons and Northern Europeans who settled the northern and midwestern regions of the United States were largely farmers, and they brought with them cultural traditions that were more oriented toward cooperation and the rule of law, compared to the Scots-Welsh-Irish (Fischer, 1989).

These three lines of scholarship laid the foundation for Nisbett and Cohen's (1996) hypothesis that high levels of violence and homicide in the American South can be explained in terms of a culture of honor. They argued that cultures of honor are most commonly found in ecological contexts in which (1) resources are scarce and individuals' possessions are easily appropriated by others, and (2) law enforcement is weak or absent and so cannot easily prevent or punish theft (see also Schneider, 1971). These conditions are common in regions where the chief source of subsistence is herding animals; such ecologies are often ill-suited for intensive agriculture, because they are arid, rocky, or mountainous. In these regions, resources are often scarce, so raiding of herds is common; and the space needed to maintain a herd results in low population densities and thereby lower levels of police presence compared to other contexts. Ecologies that are used to graze animals are also difficult to police due to lack of access, mountainous terrain, or long distances between settlements. As a result, owners of herds must present an image of strength and a willingness to retaliate against any possible threat to their possessions. A man's reputation for vigorous, aggressive responses to any threat, real or perceived, leads others to have second thoughts about messing with him and his possessions. The crux of the culture of honor thesis is that the values, beliefs, norms, and practices brought to the American South by the Celtic peoples of the Scots, Irish, and Welsh borderlands have persisted and account for regional differences in some forms of violence (Nisbett, 1993; Nisbett & Cohen, 1996; Nisbett, Polly, & Lang, 1995). As we summarize later in the chapter, Nisbett and Cohen (1996) found support for this thesis in a series of archival, experimental, and survey-based studies.

THEORETICAL FRAMEWORK FOR HONOR AND DIGNITY CULTURES

More recently, Leung and Cohen (2011) articulated a formulation that distinguishes cultures of honor from nonhonor (or *dignity*) cultures of Northern Europe and the Northern and Midwestern United States (as well as *face* cultures of East Asia, but we leave that discussion for another time). Following the work of Triandis (1994), they depict honor and dignity as cultural syndromes that are “*constellations* of shared beliefs, values, behaviors, practices and so on that are organized around a central theme” (p. 508, emphasis in original). These diverse components of the cultural syndrome become part of a *cultural logic* that makes the varied elements (beliefs, values, practices, etc.) fit together into a coherent whole (at least from the perspective of members of that cultural group). The cultural logic of honor cultures is based on conceptions of individual worth as both internal to the individual and external (in others’ appraisals), that worth (honor) can be lost, and that good behavior comes from a desire to avoid shame (for personal failures) or retaliation (for affronts to others). Due to their origins in lawless environments, immediate responses to affront, or *payback*, creates a strong norm of reciprocity, which results in both positive reciprocity (returning gifts or hospitality) and negative reciprocity (retaliation for insults or harm). Leung and Cohen contend that reciprocity and reputation are so important in cultures of honor that they lead to short-term irrationality. People may not count the costs and hardships involved in paying back an insult or returning a favor, because the burden of the obligation (to retaliate or to reciprocate) weighs so heavily.

Nisbett and Cohen’s (1996) earliest research contrasted the culture of honor in the Southern United States with the Northern and Midwestern regions of the country, where different patterns of settlement and farming-based means of subsistence shaped a cultural logic that focused on collaboration with others (rather than competition). These regions of the United States reflect the cultural norms and values of their Northern and Western European settlers. Although honor was an important legal and social construct in much of Western Europe from the 12th–18th centuries (Bowman, 2006; Stewart, 1994), by the 18th century, the internal, self-respect and personal integrity component of honor began to dominate and

the external, reputation-related component began to fade in importance. By the mid-20th century, notions of honor based on virtue, manliness, or hierarchy in Western European and Northern United States contexts had given way to ideals of equality and concerns for the dignity and rights of the individual, without respect to the person's position in society (Berger, Berger, & Kellner, 1973). Thus, the term "dignity culture" began to be applied to societies that affirmed individual human rights, equality, and the supremacy of personal characteristics over identity-based on social roles, status, or family and group memberships.

In the cultural logic of dignity cultures, individuals are presumed to have inherent worth that is not "losable" like honor (Stewart, 1994). Instead, dignity is like an "internal skeleton" (Ayers, 1984); it is the person's moral center and the core of identity. A strong sense of dignity, or of personal identity, allows the individual's behavior to be self-determined and guided by the person's own values, beliefs, and moral standards. Individual behavior is therefore constrained by guilt over failure to act in accord with one's personal standards (in contrast to the shame of public reprobation in honor cultures), and is backed up by an adequate system of law enforcement. Leung and Cohen (2011) go on to characterize dignity cultures typically as having strong rule of law that protects individuals (as opposed to the bonds of reciprocity in honor cultures). Vengeance for wrongs is taken out of the hands of the individual and given to the state; thus, reciprocity and retaliation have lost their strong salience in these societies (Miller, 1993).

These descriptions represent "ideal" types of honor or dignity cultures. In this view, a particular context is characterized as an honor culture or not; if it is not an honor culture, then it is another kind of culture (perhaps a dignity culture or a face culture, as in East Asia). For example, anthropologists have described cultures that ring the Mediterranean as honor cultures (Peristiany, 1965). This perspective is also reflected in research on subcultures of honor, such as inner-city gangs (E. Anderson, 1994) or Mafiosi (D'Andrade, 2002). Others have conceptualized honor cultures in terms of a single dimension on which multiple countries or societies may be arrayed (from highly honor-oriented to weakly honor-oriented). No single attribute of a society marks it as an honor culture, so scholars have used combinations of multiple factors as proxies for such a dimension. These have included measures such as the degree of economic

precariousness that requires vigilant defense of one's property and the trustworthiness of police protection (Alzheimer, 2012), and the degree of settlement by herders or by immigrants from the Scots–Irish borderlands (e.g., Baller, Zevenbergen, & Messner, 2009).

One could argue that the situations that create honor-related norms are available in many cultures but may not be as accessible in some contexts as in others. For example, if vigilance for threats to one's reputation is a key element of an honor-related context, then this concern could be primed among members of dignity cultures, who may then behave similarly to people who have been part of honor cultures their entire lives (IJzerman & Cohen, 2011; for further description of this conception of culture as situated cognition, see Oyserman, 2011; Oyserman & Yan, [Chapter 20](#), this volume). Finally, others have conceptualized honor cultures in terms of individual differences in the endorsement of the elements that make up the cultural logic of honor cultures (e.g., concern for reputation and retribution). Given this view, honor cultures would be those contexts composed of people who highly endorse these elements. Various measures of honor-related concerns or ideologies have been created to assess individual differences and to examine their role in honor-related behavior (e.g., Barnes, Brown, & Osterman, 2012a; Rodriguez Mosquera, Manstead, & Fischer, 2002b; Saucier & McManus, 2014). Attention to individual differences also permits researchers to tap variation in endorsement of the cultural logic within a group, and to identify when and where the prototypical values of a community are most likely to shape individual behavior (Leung & Cohen, 2011).

REVIEW AND ASSESSMENT

In the two decades that have passed since the publication of Nisbett and Cohen's (1996) first work on cultures of honor, their theoretical formulation has generated considerable new research and has become a prominent perspective for understanding cultural variation. It has been especially useful in helping researchers go beyond the earlier trends in cultural psychology that focused primarily on the cultural dimension of individualism–collectivism (or its individual-level equivalent of

independent–interdependent self-construals; Markus & Hamedani, [Chapter 1](#), this volume; Markus & Kitayama, 1991; Triandis, 1995). Certainly, the culture of honor thesis is not independent of individualism–collectivism (in fact, Vandello & Cohen, 1999, demonstrated that the U.S. South is more collectivist than the U.S. North), but, just as a microscope illuminates objects too small to be seen by the naked eye, it clarified regional patterns of behavior that were not readily detected by other cultural lenses. For example, a growing literature has begun to demonstrate key differences among collectivistic “face” cultures (e.g., Japan or China) and collectivistic honor cultures (e.g., Turkey or Pakistan; Leung & Cohen, 2011; Boiger, Güngör, Karasawa, & Mesquita, 2014; Uskul, Oyserman, Schwarz, Lee, & Xu, 2013). Compared to honor cultures, face cultures are more strongly marked by concerns for hierarchy, humility, and harmony (Leung & Cohen, 2011). In face cultures, strong social norms and attitudes lead people to avoid conflict; when an offense occurs, the group or a higher-status person takes responsibility for meting out punishment, not the victim of the offense. Although honor and face cultures may both be viewed as relatively collectivistic, they vary considerably in the ways reputation and social status are maintained (through retaliation vs. humility and harmony) and attitudes toward conflict. Finally, the culture of honor thesis is a very useful lens for examining underresearched regions of the world, such as circum-Mediterranean, the Middle East, and Latin America.

In the sections that follow, we first describe components of honor that have been revealed in research, then review research that has used the theoretical lens of the culture of honor to explain variation in interpersonal behavior—especially violence and aggression—and associated emotion. Finally, we provide observations on the state of the research and suggest future directions for research in cultures of honor.

COMPONENTS OF HONOR

From the earliest description of honor by social scientists, the construct has been viewed as having multiple components. Pitt-Rivers’s (1965) definition of honor as “the value of a person in his own eyes, but also in the eyes of his society” (p. 21) articulates two central dimensions: the individual’s own

perceptions of worth and others' evaluations of the person's worth. This definition, however, is mute as to the basis for these evaluations of a person's worth. Pitt-Rivers elaborated by explicitly linking honor to an individual's conduct, then linking conduct to others' evaluations. The expectations or standards of a cultural group for its members' behavior have been called an "honor code" (Peristiany, 1965; Pitt-Rivers, 1965; Stewart, 1994). The content of the honor code for different cultural groups varies, but some features are consistent across most contexts. Honor based on individual, personal behavior has sometimes been referred to as horizontal honor," or "honor-as-virtue" (Pitt-Rivers, 1965; Stewart, 1994). In addition, individuals may also be respected by others based on their position, status, wealth, or achievements. This form of honor has been termed "vertical honor" or "honor as precedence." This vertical form of honor is reflected in respect for the ingroup-relevant authorities, deference to elderly persons, and attention to hierarchies and status (Henry, 2009; Salzman, 2008).

In the following description of research on components of honor, we focus primarily on the features or components that contribute to horizontal honor, or honor-as-virtue, as this is the focus of most research to date.

Self-Image and Social Image

The two components of honor identified by Pitt-Rivers (1965) and Peristiany (1965)—self-image and social image—are the most commonly assessed components in subsequent research. Self-esteem, or self-respect, is the component that is most strongly shared between honor and nonhonor (or dignity) cultures. For example, when Rodriguez Mosquera and colleagues asked young people (ages 12–23) from Spain (an honor culture) and the Netherlands (a dignity culture) to answer the question "What does honor mean to you?" members of both groups generated a similar proportion of responses related to one's sense of worth or self-image (Rodriguez Mosquera, Manstead, & Fischer, 2002a). Similarly, a prototype analysis of features of honor generated by Turkish (an honor culture) and Northern American (a dignity culture) college students revealed that self-respect was one of three factors that was central in both cultural contexts (Cross et al., 2014).

Honor and dignity cultures are most strongly differentiated by the importance of social image (Fischer, Manstead, & Rodriguez Mosquera, 1999). In dignity cultures, individuals are encouraged to construct a self-view that is independent of others' views and evaluations (although the likelihood that one could actually do this is questionable). Encouragement to disregard the taunts or insults of others is reflected in children's sayings such as "Sticks and stones may break my bones but words will never hurt me." In contrast, children in cultures of honor are socialized to develop a concern for others' opinions, represented by a sense of shame (Abu-Lughod, 1999; Kağıtçıbaşı & Sunar, 1992; Taylor & Oskay, 1995; Yağmurlu, Çıtlak, Dost, & Leyendecker, 2009). Children who misbehave are often chided with statements such as "Shame on you! What will other people think of you?" Consequently, members of honor cultures are much more concerned about how others will evaluate their behavior; therefore, they are more likely to behave in ways that protect or maintain their social image compared to members of dignity cultures (D. Cohen, Nisbett, Bowdle, & Schwarz, 1996). The person who fails to do so may be ostracized from important groups, gossiped about, and discriminated against (Sev'er & Yurdakul, 2001; Wikan, 2008).

Support for social image as a key component of the concept of honor comes from many sources. When asked to describe situations that would threaten a person's honor, Turkish participants were more likely than Northern U.S. participants to describe situations that included an audience or an event that included a social group (Uskul, Cross, Sunbay, Gerçek-Swing, & Ataca, 2012). Furthermore, Turkish participants generated more situations that involved false accusations than did the northern U.S. participants; to be accused falsely of cheating, for example, stains one's social image. When asked to describe situations that could enhance a person's honor, Turkish participants were more likely than Northern U.S. participants to list situations that involved being praised or appreciated by others (Uskul et al., 2012). Social image or respect was one of three factors that emerged in the Cross et al. (2014) prototype analysis of features of honor in Turkish and Northern U.S. contexts (see also the Honor Values Scale of Rodriguez Mosquera, Fischer, Manstead, & Zaalberg, 2008). Behaviorally, insulted men from the U.S. South are more likely than men from the U.S. North to engage in dominance-related behaviors that would

repair one's social image as masculine, tough, and not to be messed with (D. Cohen et al., 1996).

Moral Behavior

Implicit in the conceptualization of honor is a foundation of personal behavior and morality, or the "honor code." Stewart (1994, p. 55) describes the honor code as "a set of standards that has been picked out as having particular importance, that measures an individual's worth along some profoundly significant dimensions; and a member of the honor group who fails to meet these standards is viewed not just as inferior but often also as despicable." Honor codes observed by anthropologists in the Mediterranean region included attributes related to fairness and justice, hospitality, and protection of one's family (Pitt-Rivers, 1965). Importantly, there are different honor codes for men and women; traditionally, men were expected to demonstrate strength, toughness, and swift retaliation against threats, along with virility and sexual potency; women were expected to demonstrate modesty, chastity, sexual fidelity, and obedience to authority (Campbell, 1964; Gilmore, 1987; Rodriguez Mosquera, 2011; Peristiany, 1965; Pitt-Rivers, 1977; Schneider, 1971). We review this literature later, but here we briefly survey the literature that connects honor to moral attributes.

The importance of integrity and virtuous behavior is in many ways the bedrock of cultures of honor, especially with regard to horizontal honor or honor among equals. The scoundrel, liar, or thief cannot be considered honorable. Instead, the honorable person is trustworthy, hospitable, honest, and true to his or her word (Rodriguez Mosquera et al., 2002a). D. Cohen and Leung (2012, p. 162, emphasis in original) describe the role these attributes play in the development of cultures of honor, where law enforcement was often weak: "In lawless environments, . . . it is good to be known as someone who will pay back both his threats and his debts—[one] who has the backbone to stand up for himself and his rights and the backbone to *do* what is right (rather than merely expedient)."

Consistent with the centrality of integrity in conceptions of honor, recent research in Turkey and the Northern United States has shown that behaviors such as honesty and trustworthiness are central to conceptions of

honor in these cultural contexts (Cross et al., 2014). In fact, when asked to describe the concept of “honor,” both Turkish and Northern U.S. participants listed *honesty* or *trustworthiness* as one of the most central features of the concept of honor. Similarly, Uskul et al. (2012) found that when asked to describe how a person’s honor can be threatened, Turkish participants were more likely than Northern U.S. participants to generate situations that unfairly attacked a person’s integrity or moral behavior.

One characteristic of the integrity component of honor is reciprocity. As mentioned earlier, cultures of honor originated in lawless environments in which men had to develop a reputation as reliable, trustworthy partners, along with a reputation for swift and strong response to wrongs and injustices. Thus, a good person in a culture of honor pays back both positive actions (e.g., reciprocating a gift) and negative affronts (retaliating against the source of a wrong; Nisbett & Cohen, 1996). In contrast, in dignity cultures, exchanges are marked by a contractual orientation backed up by individuals’ commitment to their own personal standards of honesty and a rule of law that enforces contracts. The role of reciprocity in honor versus dignity cultures was examined by Leung and Cohen (2011), who found that endorsement of honor-related aggression (retaliation after an insult) was positively related to returning a favor among members of honor cultures (U.S. Latinos and Southern Anglos), but not among members of a dignity culture (Northern Anglos).

In a culture of honor, the virtue component of honor is woven together with other components of honor, including masculine honor. One place where the attributes of masculine honor—strength, physical courage, and the defense of one’s group—is most highly institutionalized is in the military. D. Cohen and Leung (2012) examined historians’ and other experts’ ratings of U.S. presidents, legislators, and Supreme Court Justices for their character and integrity, moral courage, and military experience. For all three groups, they found that involvement in the military (especially leadership positions) positively predicted high levels of integrity or moral leadership among Southern, but not Northern, political figures. These findings suggest that in cultures of honor, an honest man who is not willing to fight for what is right is not an honorable man. In contrast, among members of dignity cultures, a man of virtue and integrity does not have to engage in physical aggression or

violence to be considered honorable (see also Barnes, Brown, & Osterman, 2012a; D. Cohen et al., 1996).

Individual acts of honesty, courage, or reciprocity are not the only ways that moral values penetrate the honor code; behaviors that enhance the standing of one's family or ingroups and vigorous responses to threats to the reputation of one's ingroups are also critical to conceptions of the honorable person in cultures of honor. We address this element of honor later in the chapter. For now, the research on morality and honor can be summarized this way: In a culture of honor, the dishonorable person has not just made a mistake or done something bad that is known by others, he or she is *immoral*, contaminated, and, in the words of Stewart (1994, p. 55), "viewed not just as inferior but often also as despicable." Much as sin in Judaism and Christianity requires atonement, so also a threat to one's honor requires an action that in some way "cleanses the stain" of dishonor (Ginat, 1997).

Honor as Precedence

As we mentioned above, anthropologists also described honor in terms of status and hierarchy, with high-status individuals or families accorded more respect than others (Pitt-Rivers, 1965; Salzman, 2008). In his description of Bedouin blood feuds between families, Kressel (1996) pits the material costs of such conflicts against the intangible benefits of victory that bring "enhanced self-image concomitant with hierarchical status . . . in a society that values family honor over economic achievements, [greater] deference more than compensates for the lack of material rewards" (p. 158). Henry (2009) addressed this component of honor in his theory of *low-status compensation*. Drawing on the early work by Nisbett and Cohen (1996), he argued that the link between herding societies and violent self-defense is attributable to status disparities in these societies and the desire of low status-group members to bolster their threatened self-worth. Low-status group members perceive themselves as stigmatized and experience defensiveness in their social interactions, which tends to translate into aggressive behaviors. When lower-status participants have the opportunity to affirm their self-worth, however, they are less likely to show aggression when disrespected (Henry, 2009).

Gendered Components of Honor

Reputational concerns in honor cultures not only revolve around integrity, virtue and good moral character, but also tend to be gender-specific and include different honor codes for men and women. As noted earlier, for men, having honor means maintaining a reputation for strength, toughness, courage, vigilance in defending oneself from insults, willingness to protect one's women, and authority over family. For women, having honor means maintaining a reputation for sexual purity, chastity, and loyalty to men and family (Campbell, 1964; Gilmore, 1987; Rodriguez Mosquera, 2011; Peristiany, 1965; Pitt-Rivers, 1977; Schneider, 1971). Even though these gendered honor codes are part of traditional gender roles that exist nearly in all cultures worldwide (Gilmore, 1990; Rodriguez Mosquera, 2011), honor cultures exacerbate the importance of their inhabitants' complying with these gender roles (Bosson & Vandello, 2011; Vandello & Cohen, 2008). The proximal reason for honor cultures to place high value and expectations on men's and women's adherence to their gendered honor codes is related to the costly consequences associated with losing honor. Failure of individuals to fulfill their gendered honor codes brings shame upon the individual and his or her family, and may have detrimental consequences for self-esteem, health and well-being (e.g., Mahalingam & Leu, 2015; Sev'er & Yurdakul, 2001; Vandello & Cohen, 2003, 2008). Because of honor's precarious status and the potentially costly consequences associated with losing honor, both men and women in cultures of honor are sensitive to threats to their honor. They engage in a variety of behaviors to maintain and protect it, and once it is tarnished, to reaffirm their honor.

Traditional honor cultures tend to be also highly patriarchal, subordinating women and exerting control over their sexuality (Glick, Sakalli-Ugurlu, Akbas, Metin Orta, & Ceylan, 2016; Sev'er & Yurdakul, 2001). In honor cultures, a man's reputation depends not only on his own behavior but also that of his women (wives, sisters, daughters, etc.), especially their sexuality. Men are held responsible for guarding women's behavior to ensure that they remain sexually pure and loyal to the men in their family. An Arab expression captures this aspect of the gendered honor code starkly: "Man's honor lies between the legs of a woman" (Beyer, 1999, p. 55). Because of these patriarchal dynamics of honor cultures, women's

failure to adhere to their honor codes can provoke extreme shame and anger in the family. The relatively high rates of violence against women (e.g., honor killings) in honor cultures is related to male control over women's sexuality, and it is used to deter women from infidelity or sexual indiscretions, and to punish them to restore the family's lost honor (Baldry, Pagliaro, & Porcaro, 2013; Caffaro, Ferraris, & Schmidt, 2014; Cihangir, 2013; Eisner & Ghuneim, 2013; Sev'er, 2005; Sev'er & Yurdakul, 2001; Vandello & Cohen, 2008).

Several social psychologists have investigated the degree to which gender-specific honor codes are endorsed by men and women living in honor versus dignity cultures. For instance, Cihangir (2013) found that Turkish and Moroccan ethnic/minority men in the Netherlands identified sexual purity of a female family member as more important to their own honor and felt more responsible to protect it than did native Dutch men (representative of a dignity culture). Another study comparing Chileans and Canadians showed that Chileans (an honor culture) agreed with gender-specific honor codes ("A man must defend his honor at all costs," "A woman's honor must be defended by the men in the family") more than did Canadians (a dignity culture). Compared to the Canadians, Chilean men and women also thought that it was more important for their sons and daughters to have honor-related qualities such as being pure, respected by others, having a spirit of sacrifice (for the daughters), and being masculine (for the sons) (Vandello, Cohen, Grandon, & Franiuk, 2009). However, other research failed to find cultural differences in the endorsement of gender-specific honor concerns. For example, Rodriguez Mosquera et al. (2002a) found that Spanish and Dutch men and women reported comparable levels of concern for maintaining their respective gender-specific honor (also see Rodriguez Mosquera, 2011, for similar findings). These authors interpreted this result as reflecting the change in contemporary Spain, where gender egalitarian attitudes have become more commonplace, especially among university students. Importantly, studies examining sex differences in the endorsement of gender-specific honor codes within honor cultures (Turkey, Southern United States) revealed that men significantly report higher levels of adherence to masculine and feminine honor codes than do women (i.e., believing that men and women should adhere to masculine and feminine honor codes, respectively, not how much they individually adhere to those codes) (Glick et al., 2016; Saucier, Strain, Hockett, & McManus, 2015;

Saucier et al., 2016). These results reflect men's willingness to maintain personal reputations for strength, toughness, and courage, as well as their expectations for their female family members to remain sexually pure and loyal, which ultimately may reflect on the men's reputation.

Even though Nisbett and Cohen (1996) mentioned that women in honor cultures also play important roles in sustaining and perpetuating honor norms through socializing their sons with these values, and holding their men to honor standards, early culture of honor research has almost exclusively focused on men as the active agents of honor. More recent research reveals that women who are socialized in honor cultures may also be shaped by the general social pressure to value a reputation for strength and fearlessness. Consequently, women residing in cultures of honor might display the motives and behaviors that are similar to those of the men. For example, both men and women in honor states in the United States are more likely than those in dignity states to engage in excessive risk taking, resulting in high rates of accidental deaths (Barnes, Brown, & Tamborski, 2012b). Similarly, masculine honor mentality can have collective or national manifestations among men and women alike. Barnes et al. showed that both men and women from an honor state (Oklahoma) supported more aggressive responses to a national-level provocation than those from a dignity state (Pennsylvania). They argued that even though it might not be in women's interests to personally engage in the same violent behaviors that a culture of honor rewards among men, they still encourage and support their men's efforts to defend their country's good name from foreign attacks. This pattern of findings is further supported by large-scale cross-cultural research conducted in eight nations (Brazil, Israel, Japan, Macedonia, and Spain studied as honor cultures, and New Zealand, the United Kingdom, and the United States studied as nonhonor cultures), which revealed that attributes and characteristics associated with masculine honor, such as defending oneself from insults and an ability to support a family, are often endorsed by men and women alike (Guerra, Giner-Sorolla, & Vasiljevic, 2013; see also Rodriguez Mosquera et al., 2002a).

Together, these findings indicate that honor may influence women's attitudes and beliefs much as it does men's. Nevertheless, despite these recent research efforts, we still know very little about how living in cultures with strong honor norms influences women's motivations, emotions, and

behavior. Understanding the consequences of culture of honor in women's psychologies requires investigating outcomes that go beyond the realm of physical aggression or risk taking, which are regarded as typically masculine-typed behaviors, and examining subtler social and moral processes (e.g., relational forms of aggression).

Family Honor

A critically important component of honor is the respect and status accorded to one's family. "Family honor" refers to values and norms related to the protection and maintenance of the social image or reputation of one's family (Rodriguez Mosquera et al., 2002b) and is considered to be a central part of honor in Mediterranean, Middle Eastern, and some South Asian regions (especially Pakistan, Bangladesh, and some regions of India). Comparative research on family honor indicates that in honor cultures (Spain, Turkey), compared to nonhonor cultures (the Netherlands, Northern United States), honor is more closely related to family (Rodriguez Mosquera et al., 2002a), family honor is endorsed to a greater extent (van Osch, Breugelmans, Zeelenberg, & Bölük, 2013; Rodriguez Mosquera et al., 2002b; Shafa, Harinck, Ellemers, & Beersma, 2015), and honor-attacking situations involve family members as targets more frequently (Uskul et al., 2012). The importance put on family honor in honor cultures is also associated with important emotional, relational, and behavioral consequences. For example, compared to members of a dignity culture (European Americans), members of cultures of honor (Pakistanis) experience more intense anger and shame and greater relationship strain when their families are insulted (Rodriguez Mosquera, Tan, & Saleem, 2014). Being accused of acting as a disgraceful member of the family has a greater impact on one's self-esteem and leads to more intense shame experiences in honor cultures compared with dignity cultures (Rodriguez Mosquera et al., 2002b). Finally, in an honor culture (Turkey), greater endorsement of honor values predicts retaliatory behavior against those who attack one's parents' honor (Uskul, Cross, Gunsoy, Gercek-Swing, Aozkan, & Ataca, 2015).

In some honor cultures, family honor plays a more important role than other components of honor in explaining cultural differences in honor-relevant psychological outcomes. For example, concern for family honor (and, e.g., not masculine honor) accounted for cultural differences in the intensity of shame in response to insults that attack one's family honor (Rodriguez Mosquera et al., 2002b). Concern for family honor also accounted for cultural differences in intentions to react aggressively following an insult described in a scenario (van Osch et al., 2013). This may be because family honor taps into the interdependent characteristic of relationships in collectivistic honor cultures, increasing its explanatory power in honor-related outcomes that involve social interactions. Other research, however, failed to find such a link: Concern with family honor and involvement in violent behaviors were negatively correlated in a sample of Arab youth (Khoury-Kassabri, 2016). Note that in this study, violent behaviors were measured as general delinquent behaviors and not as aggressive acts against honor attacks such as insults, suggesting that a strong concern with family honor may encourage individuals to stay away from deviant violent behaviors that might damage family reputation.

In line with a strong overlap between the self and close others documented in many collectivistic cultures (Markus & Kitayama, 1991; Triandis, 1995), in honor cultures, one's own actions have consequences for the reputation of close others; personal honor is rooted in the actions of close others and in how they are socially evaluated (Abu-Lughod, 1999; Miller, 1993; Pitt-Rivers, 1965, 1977; Stewart, 1994; Peristiany, 1965). Thus, honor is contagious—an attack on an individual's honor is felt to be an attack on the whole family (and even the larger social identity groups, such as religious groups, gender groups, and society; see Gelfand et al., 2012; Lee, Gelfand, & Shteynberg, 2013). Research supports this strong overlap between personal and family honor. Individuals of Turkish origin view honor-relevant situations as having a similar impact on one's own feelings and the feelings of family members (compared to Northern U.S. individuals, who evaluate these situations as having a greater impact on one's own feelings than on the feelings of family members; Uskul et al., 2012). Similarly, among members of Pakistani culture, insults directed to parents and to oneself elicit similar emotional responses (compared to European Americans, who responded more negatively to an insult directed to the self

than to parents; Rodriguez Mosquera et al., 2014). Family honor is considered to be the strongest foundation of honor-related violence, mostly committed against female members of the family, with a goal to protect and maintain the family's honor when it is believed to be stained by real or merely alleged dishonorable conduct (Cooney, 2014; Sev'er & Yurdakul, 2001). Thus, it is heavily intertwined with gendered norms of honor, with the feminine honor code requiring loyalty, sexual purity, and modest behavior, and the masculine honor code requiring ability to protect family honor by successfully overseeing behaviors of female family members (e.g., Rodriguez Mosquera et al., 2002b; Vandello & Cohen, 2003).

Summary

The construct of honor comprises multiple components: self-respect, social respect, moral behavior, precedence or status, gendered codes, and family honor. To focus on any of these in isolation would be shortsighted; they are a complex interdependent system of values, beliefs, ideals, motives, and practices—a *cultural logic* that makes most sense when viewed as a whole. In the following sections, we address how the cultural logic of honor cultures compared to the cultural logic of dignity cultures, and shapes behavior and emotions.

BEHAVIORAL AND PSYCHOLOGICAL CONSEQUENCES OF HONOR

In this section, we review research that examines psychological and behavioral consequences of honor, with a focus on retaliation after honor threats, expressed in violence and aggression, politeness, and honor-related emotions.

Honor Cultures and Retaliation

As we summarized earlier, honor cultures are societies in which defense of reputation is a core theme (Leung & Cohen, 2011; Nisbett & Cohen, 1996;

Peristiany, 1965). Members of honor cultures (especially men) aim to create and maintain reputations for strength and toughness, and they strive to be prepared to engage in aggressive actions when their honor faces a threat (Nisbett & Cohen, 1996). The social-psychological literature on honor has, for the most part, focused on understanding the role of honor in cultural differences in preference for violence, particularly with respect to regional differences in the United States. There is also growing attention paid to honor crimes in different parts of the world, a topic typically associated with difficulty in establishing validity and reliability in data collection (for a review, see Kulczycki & Windle, 2011; also see B. Hayes, Freilich, & Chermak, 2016; Sev'er & Yurdakul, 2001).

In this section, we discuss the different forms of violence associated with honor concerns under three sections: interpersonal, intrapersonal, and intergroup/collective violence, covering research evidence gathered using different methodologies. Our discussion is largely informed by research that compares Southern and Northern U.S. honor states given the extensive volume of related evidence, but we also cover evidence, when available, from other parts of the world.

Interpersonal Violence

Archival and Social-Structural Evidence

There is plenty of archival research demonstrating that the Southern United States is more violent than the Northern United States when it comes to causes related to reputation and threat. For instance, argument-related (rather than felony-related) homicide rates among white males living in rural areas and small towns (where one's reputation is likely to be of particular concern) in the Southern United States are higher than among their counterparts living in the Northern United States (Ayers, 1991; Nisbett & Cohen, 1996). Moreover, the proportion of Southern-born individuals is also predictive of White homicide rates in non-Southern states (M. Lee, Bankston, Hayes, & Thomas, 2007; for the relationship between the Southern subculture of violence index and female homicide offenders, see M. Lee, Thomas, & Ousey, 2010; Doucet, D'Antonio-Del Rio, & Chauvin, 2014).

Other evidence points to the existence of a variety of culture of honor norms that govern the contemporary Southern United States. For example, Southern states have higher rates of executions, violent television viewership, violent magazine subscription rates, and hunting licenses per capita (Baron & Straus, 1989). Southern and Western states are also more likely to have more permissive gun control legislation, representatives who vote for more hawkish foreign policies, more lenient laws toward domestic violence, greater tolerance for corporal punishment in schools, and self-defense laws that result in milder sentences for people who use violence in defense of self or property (e.g., shooting of an intruder; D. Cohen, 1996; Nisbett & Cohen, 1996). These observations suggest that laws and social policies in the South and the West are more favorable toward violence committed to maintain and protect one's honor; collective representations and cultural products of the region also follow suit. Moreover, in line with the finding that argument-related homicides are more common in rural areas and small towns of the southern states (Nisbett & Cohen, 1996), D. Cohen (1998) observed that higher levels of social organization (defined by residential and family stability) is associated with more violence and more violent policies in the South, whereas these associations are reversed for the Northern United States. Cohen argued this is because an individual's social reputation is more easily threatened and norms regarding honor codes are more easily transmitted and enforced in stable families and communities.

There is evidence that retaliatory violence is not restricted to adults only, but can also be seen among children and adolescents in honor states. Recently, Brown, Osterman, and Barnes (2009) found that both the percentage of high school students who reported having brought a weapon to school in the past month and the number of actual shootings were higher (to be exact, three times higher) in the honor states of the United States than in the nonhonor states. These regional differences remained when a list of relevant state-level demographic variables were statistically controlled (e.g., temperature, median income).

D. Cohen et al. (1996), drawing on previous insights from Wyatt-Brown (1982, 1986) and McWhiney (1988), among others, argued that the observed regional differences in violence cannot be predicted by regional differences in temperature, poverty, or the institution of slavery, as other social scientists have argued, but are linked to a culture of honor deriving

from a herding economy that has dominated the South. Some have failed to establish this link empirically (e.g., Chu, Rivera, & Loftin, 2000; Loftin & McDowall, 2003; Rivera, Chu, & Loftin, 2002) and have suggested that the use of direct measures and historical indices of herding versus farming could provide a more stringent test of the herding hypothesis. Studies that were conducted with a much tighter focus on the farmer versus herder distinction and using historical indices have indeed provided support for the herding hypothesis. For example, Reaves (1992), in a direct test of the herding hypothesis, examined rates of white male homicide in the hills and dry regions that are more appropriate for herding versus the moist plains that are more appropriate for farming. He found that white male homicide rates were substantially higher in herding regions than in farming regions. Furthermore, in an attempt to test the lasting effect of herding in the contemporary Southern United States, Messner, Baller, and Zevenbergen (2005) used two historical indices, measures of religious affiliation and agricultural production, as proxies for the prevalence of herding populations in the South. They found that, in line with the thesis put forward by Nisbett and Cohen (1996), counties and county clusters that relied more heavily on agriculture than herding in the 19th century showed lower levels of contemporary homicide by white men, controlling for a variety of structural variables.

More recently, Baller et al. (2009) found that the percentage of Presbyterian churches in 1850 (a proxy for presence of Scots-Irish communities) was positively associated with argument-related homicide in parts of the U.S. South with high herding activity (i.e., higher numbers of cattle and pigs). They also found that argument-related homicide occurred less in parts of the South with high agricultural activity (i.e., that were more dependent on the production of crops in 1850), again providing supportive evidence of the role of herding as the ecological underpinning of a code of honor in the U.S. South. Additional support for the herding-culture of honor link comes from Grosjean (2014), who combined data on crime from the Uniform Crime Reporting program in the United States and on historical settlements from the U.S. Census to test the hypothesis that high prevalence of homicide rates in the U.S. South is due to settlement by herders in this region. She found that historical Scots-Irish presence is associated with higher rates of homicide (particularly by white offenders)

and that a culture of violence was transmitted to subsequent generations in the South and where quality of institutions was historically weak (defined by age of the state and the number of newspapers per capita). Finally, in a cross-cultural study involving 51 nations, Altheimer (2012) examined the argument that scarcity of resources and absence of strong law reinforcement should be related to the emergence of a culture of honor. He found that a culture of honor proxy created based on six measures tapping into economic precariousness and the inability or unwillingness of the state to provide protection from others significantly predicted homicide rates across nations. This study is the first to test Nisbett and Cohen's (1996) arguments at a macro level across nations, and it provides evidence for the generalizability of the culture of honor hypothesis to contexts outside of the United States.

Attitudinal Evidence

The archival and structural evidence documenting greater levels of violence (and its tolerance in regional structures) has been complemented by studies based on analyses of existing survey data showing that Southern white males are more likely than Northerners to endorse violence when it is used for self-protection (e.g., a man has the right to kill a person to defend his house) and to defend their honor (e.g., violent response to an insult is justified; D. Cohen & Nisbett, 1994). Crucially, this regional difference in endorsement of violence does not generalize to arbitrary use of violence, which suggests that Southerners tend to view violence as useful to serve a function, namely, to protect and restore a social image, especially when there is a threat directed against that image.

Research with other honor versus dignity cultures provides confirming evidence for the pattern observed in comparative work originating in the United States. In one study, when asked how they would respond in different situations involving an insult or rude behavior, Turkish participants reported that they would respond more aggressively than did Dutch participants (van Osch et al., 2013, Study 1). In another study, Turkish Dutch participants primed with Turkish identity (compared to those primed with their Dutch identity) reported that they would react more aggressively in a situation that involved a false accusation (van Osch et al., 2013, Study

2). Cihangir (2013) found that Turkish and Moroccan ethnic/minority men in the Netherlands endorsed violence against themselves by their family if they were to violate their family's honor more than did their female counterparts, and also more than did native Dutch men.

Observations about positive attitudes toward honor-related violence at the individual level are mirrored in attitudes at the institutional level. For example, employers in honor states were more understanding and cooperative to job candidates with criminal records in honor-related conflict than employers in nonhonor states (D. Cohen & Nisbett, 1997). In a similar vein, newspapers in honor states produced stories more sympathetic to the perpetrator when the crime was committed in response to a family insult than did newspapers in nonhonor states (D. Cohen & Nisbett, 1997). Once more, differences in attitudes between honor and nonhonor states emerged in relation to honor-related violence, and not in relation to other types of violence. In a within-culture study, Baldry, Pagliaro, and Porcaro (2013) showed that when given a real police intervention case of intimate partner violence coupled with a reference to the victim's admission of an affair with another man (vs. no affair), Afghan police officers showed more lenient attitudes toward violence against the female victim, which was associated with reduced intentions to intervene in the form of reduced willingness to arrest the male perpetrator and to provide support to the female victim. This study demonstrates how the concerns over masculine honor can take precedence over women's rights.

In line with the gendered characteristics of honor cultures, the patriarchal dynamics embedded within cultures of honor are associated with more tolerance and acceptance of domestic violence. Vandello and Cohen (2003) compared residents of Brazil (an honor culture) and the Northern United States (a dignity culture) with regard to their evaluations of husbands and wives in the context of female infidelity. They found that Brazilian participants reported that female infidelity caused greater damage to a male's reputation than did participants from dignity cultures. Compared to U.S. Northerners, Brazilians were more likely to judge a man who responded with violence to his unfaithful partner as honorable (manly, strong, and trustworthy) and his actions as positive, and they were more likely to view a woman who remained loyal in the face of jealousy-related violence favorably (nicer, stronger, more agentic; see Vandello et al., 2009). In addition,

Vandello et al. found that participants from honor cultures (e.g., Latinos and U.S. Southerners) evaluated a woman who remained in an abusive relationship more favorably than did participants from dignity cultures (e.g., U.S. Northerners and Canadians). These findings not only highlight the importance of reputation for both men and women in honor cultures but also demonstrate that the reputational focus for women in a culture of honor is on sexual purity and loyalty, as discussed in the earlier gendered component section.

Finally, in a study in Amman, Jordan of attitudes toward and potential predictors of honor crimes (acts of violence committed against female family members who are perceived to have stained the family's honor), Eisner and Ghuneim (2013) found that 40% of adolescent boys and 20% of adolescent girls (especially those from lower socioeconomic backgrounds and more traditional family backgrounds) considered it acceptable to kill a female family member who has dishonored the family, once again confirming that violence is viewed as a useful tool to protect female chastity and, by implication, family honor. Three proximal variables predicted attitudes toward honor crimes: traditionalism, belief in female chastity, and a general tendency to morally neutralize aggressive behaviors. Importantly, religion or intensity of religious beliefs did *not* predict attitudes toward honor crimes. Finally, in a study of attitudes toward honor killing in different hypothetical versions of adultery, Caffaro et al. (2014) found that, overall, Turkish, compared to Italian, participants attributed more responsibility to the victim and less responsibility to the perpetrator, and proposed less severe punishment for the perpetrator.

Experimental Evidence

Archival and attitudinal evidence is no doubt helpful in identifying differences between members of honor cultures and dignity cultures, but they are limited in demonstrating and explaining cultural differences in actual honor-relevant behaviors. Moreover, given the sensitivity of the topic investigated, findings based on self-report, as in attitudinal evidence, are subject to social desirability effects. Thus, to augment the evidence summarized earlier with observations of behavioral evidence in more controlled settings, D. Cohen and colleagues (1996) conducted a set of

laboratory studies in which Southern and Northern male participants were bumped by a confederate in a narrow hallway while being called “asshole” by him. They found that following the insult, Southern participants were more likely to (1) feel more upset, as indicated by higher cortisol levels; (2) be more cognitively primed for aggression, as shown by projective tests; (3) believe that the insult threatened their masculinity; (4) show physiological readiness for aggression, as indicated by their testosterone levels; and (5) actually engage in aggressive displays, as indicated by a firmer handshake and waiting longer to give way to the confederate. These differences were argued to have arisen due to Southerners’ feeling more insulted after the affront and having different rules for responding to an affront compared to Northerners. Importantly, Southern and Northern participants did not differ in their responses in the absence of an insult; if anything, unprovoked Southerners were the most polite and deferential.

Experimental research in the context of domestic violence provides evidence in line with the attitudinal findings we summarized earlier. To investigate how “proper” behavior might get transmitted and reinforced in the relational dynamics involving men and women in honor and dignity cultures, Vandello and Cohen (2003) created a situation in the laboratory in which participants witnessed a couple that ostensibly experienced a physical confrontation, then interacted with the woman to give her advice. Cultural differences emerged in participants’ private evaluations of the woman and their direct communication with her. Latinos and Southern Anglos were more favorable to the woman when she expressed loyalty to her partner (vs. intolerance and independence); Northern participants showed the opposite effect (and evaluated the woman who stayed as weak). Interestingly, there were no gender differences in these findings, which suggests that both men and women in each cultural group share similar cultural expectations surrounding how women should behave in abusive relationships.

Recent research shows that higher levels of violence in response to threats are not limited to U.S. Southerners’ versus Northerners’ differences. Uskul and colleagues (2015) studied retaliatory responses to actual honor threats among Turkish and Northern U.S. participants, moving beyond the typically studied threats to masculinity and focusing on accusations of dishonesty as threats to honor (see Uskul et al., 2012). In their studies, participants wrote an essay describing the role of honesty in their lives and

received feedback on their essay, accusing them of being dishonest (vs. neutral feedback). Turkish participants retaliated more aggressively than did Northern U.S. participants to the person who provided the feedback critical of their honesty, by assigning this person to solve more difficult tangrams over easy ones or to complete unpleasant sensory tasks of a higher level of intensity.

Intrapersonal Violence

Recent research shows that norms in cultures of honor may not only shape interpersonal violence but may also have a detrimental effect on violence against oneself. Applying some of the core elements of honor cultures, such as valued traits such as self-reliance, toughness, and strength, to understanding how members of honor cultures might choose to cope with negative outcomes (e.g., failure, humiliation experiences), Osterman and Brown (2011) suggested that in such cultures, a particular form of self-directed violence—suicide—might be viewed as a way out. They found that suicide rates among men and (to a lesser extent) women living in honor states in the United States were higher than rates among men and women living in dignity states. Furthermore, they also found that, compared to dignity states, depression rates in honor states were higher and medical help-seeking for depression (operationalized as antidepressant prescriptions) was lower. There was also a stronger association between depression and suicide. They reasoned that lack of appropriate help seeking in the face of mental health problems, based on a concern to avoid undermining one's reputation in the eyes of others, might contribute to social isolation and feeling burdened among members of honor cultures and increase the perception that suicide might present an answer. Moreover, perhaps ironically, suicide may be seen as a sign of courage and strength, which can help a person rectify his or her damaged social image (Osterman & Brown, 2011). Crowder and Kemmelmeier (2014) followed up on this logic and replicated the finding that higher rates of depression are related to higher levels of suicide in honor states but not in dignity states. They showed that the relation between honor culture and suicide was explained by levels of antidepressant drug prescription use and not by levels of depression,

which suggests that higher suicide rates in honor states are primarily a result of a reluctance to seek treatment for depression.

Intergroup and Collective Violence

As discussed in the section on family honor, members of honor cultures tend to be more implicated by the reputation of the groups to which they belong than are members of dignity cultures. These groups are mostly close ingroups, such as family, but may also include larger and more distant groups such as one's religious group, political groups, or national groups (e.g., T. Lee et al., 2013). Investigating whether honor concerns that have been previously linked to violent behaviors at the interpersonal level might also extend to similar behaviors at the collective level, Barnes et al. (2012a, Study 2) showed that after the terrorist attacks against the United States on 9/11, participants from an honor state, compared to participants from a dignity state, more strongly endorsed deadly retaliation against the individuals who committed the attacks. These findings overlap with D. Cohen's (1996) observation that legislators from honor states were more supportive of aggressive national security policies than their counterparts in dignity states. In a different study testing a potential mechanism for the previous finding, Barnes, Brown, Lenes, Bosson, and Carvallo (2014) found that national identification mediated the relation between honor and defensive responses to illegal immigration and terrorism. In an extension of this line of research to different national contexts, and focusing on the endorsement of group honor (rather than masculine honor), Levin, Roccas, Sidanius, and Pratto (2015) found that Lebanese and Syrians who value group honor are more likely to perceive that the U.S. government wants to dishonor them (e.g., by humiliating and disrespecting Arabs), which in turn predicted support for aggressive responses toward Americans, above and beyond other, typically researched group-related variables (social dominance orientation and right wing authoritarianism). This finding points to the potentially important role that group honor concerns may play in understanding intergroup violence.

Another example of the link between personal honor and violence at a group level comes from recent research conducted in the south of Italy,

designed to examine the role of personal honor in collective opposition against criminal organizations. In southern Italy, the Mafia operates under its own code of honor; the Mafiosi obey the principle of *omertà*, according to which individuals must be able to deal with offenses without the help of state authorities, and they must stay quiet when they witness others' illegal acts (Paoli, 2004). This region has groups that aim to decrease the power of Mafia and the related *omertà* code that operates at political, judicial, or civil society levels. This research shows that endorsement of masculine honor was associated with more positive attitudes to these criminal organizations and lower intentions to collectively oppose these organizations (Travaglino, Abrams, & Randsley de Moura, 2016). Furthermore, identification with the region (Campano region in the south of Italy) predicted endorsement of masculine honor which in turn predicted lowered intentions to oppose these criminal organizations (Travaglino, Abrams, Randsley de Moura, & Russo, 2015).

Summary

The original focus on interpersonal aggression in honor versus dignity cultures in the literature has recently been expanded to include how the cultural logic of honor may shape other forms of aggression, including intrapersonal and intergroup aggression. The majority of studies in the literature on culture of honor is conducted in the aggression domain and features a rich methodological diversity. More recently, researchers have started examining the honor-aggression link outside of the Southern versus Northern U.S. comparative context, adding evidence from different parts of the world. In the next sections, we review how members of honor cultures, known for their aggressive tendencies when their honor is at stake, paradoxically display more politeness than do members of dignity cultures.

Honor Cultures and Politeness

Paradoxically, honor cultures may be known as places of great politeness (D. Cohen & Vandello, 2004). It has been suggested that honor cultures breed norms of politeness and hospitality to prevent causing offense to others that

might potentially trigger a cycle of retaliation and retribution once a conflict erupts. Existing evidence supports this idea. In the absence of any offense, compared to members of dignity cultures, members of honor cultures show higher levels of politeness and friendliness: They give way to the other person more quickly and their handshakes are evaluated as less firm, which suggests a less aggressive, less dominant response (D. Cohen et al., 1996); they also feel reluctant to interpret a situation as involving conflict and are more willing to handle a conflict situation constructively (Harinck, Shafa, Ellemers, & Beersma, 2013). These findings are mirrored when honor is measured as an individual-difference variable: Honor concerns correlate negatively with competitive conflict intentions (Beersma, Harinck, & Gerts, 2003). Similarly, individuals whose honor concerns are activated favor a more accommodating and less dominating conflict strategy compared to those whose honor concerns are not activated (Shafa et al., 2015). Moreover, at a regional level, scores revealed that participants from U.S. Southern honor states were the most helpful in the country (Levine, Martinez, Brase, & Sorensen, 1994) and appeared less favorable toward violence than Northerners when no context is provided for violence (D. Cohen & Nisbett, 1994; also see T. Hayes & Lee, 2005). Finally, there is evidence that politeness norms may play a greater role in some offenses than others. Cross, Uskul, Gerçek-Swing, Sunbay, and Ataca (2013) observed that members of an honor culture (Turkish participants) showed more approval for a person who overlooked a rude insult (e.g., being called a vulgar name) than for a person who confronted the insulter; in contrast, Turkish participants also showed more approval for a person who confronted a false accusation (an honor threat) than for a person who walked away. This finding suggests the need for a more fine-tuned approach to understanding how politeness norms may operate across different honor-relevant situations cross-culturally.

To understand the dynamic nature of polite and aggressive responses among members of honor and dignity cultures, D. Cohen, Vandello, Puente, and Rantilla (1999, Study 1) examined how such responses may emerge in the face of accumulating minor annoyances over time. They observed that, when subjected to a series of annoyances, U.S. Southerners did not rush to respond and seemed to keep their anger under control, but when the line was crossed and they did respond, their reactions contained more

aggression and hostility than Northern U.S. individuals. Moreover, their reactions showed sudden and dramatic escalations, while the reactions of Northern U.S. individuals leveled out. They concluded that politeness in honor cultures may not simply act as signs of civility and courtesy, but may also be a way of masking anger, rendering effective communication and conflict resolution difficult, which can eventually lead to aggressive eruptions. In a county-level analysis, D. Cohen and colleagues (1999, Study 3) showed that being friendly and helpful correlated with having fewer argument-related homicides in the Northern United States, whereas such a relation was absent in the Southern United States (and in fact slightly reversed). Recent evidence from a study with individuals high and low in honor endorsement suggests that a prevention-oriented motivational orientation (as discussed by Higgins, 1997) might be the underlying motivational mechanism of this seemingly incompatible dual-nature of honor (Shafa et al., 2015, Study 2).

Honor and Emotions

Both ethnographic work and social-psychological evidence suggest that honor-relevant events are associated with strong emotional responses; the pattern of related emotional experiences shows cultural variation consistent with the central concerns in a given cultural context. The literature on honor has primarily focused on emotional consequences of negative, honor-relevant events in which one's honor is attacked via offenses or insults (e.g., D. Cohen et al., 1996; Rodriguez Mosquera et al., 2002a). A natural result of this is that we know more about how honor is linked to negative emotions, such as anger and shame, than we do about how honor is linked to positive emotions such as happiness or humility (pride is an exception here, which we will cover below). In this section, we focus on three emotions that have been the focus of studies on the honor–emotion link: anger, shame, and pride.

As we implied earlier in the section on retaliation, anger is closely related to honor. In honor cultures, compared to dignity cultures, attacks on one's honor in the form of offenses, insults, or false accusation foster strong feelings of anger, which can mobilize actions to retaliate against the

perpetrator, with a goal of restoring one's sense of honor (D. Cohen & Nisbett, 1994, 1997; D. Cohen et al., 1996; Nisbett & Cohen, 1996; Peristiany, 1965; Stewart, 1994). This seems to be especially true if the attacks target masculine honor (e.g., D. Cohen et al., 1996; IJzerman, van Dijk, & Galluci, 2007; for an exception, see Rodriguez Mosque et al., 2002b), as men in honor cultures are socialized to reject public humiliation and express anger to signal this rejection (D. Cohen & Nisbett, 1994; Peristiany, 1965; Pitt-Rivers, 1977; Stewart, 1994).

Yet other studies revealed either no cultural differences in anger or contradictory patterns. For example, when individuals are asked to reflect on a recent episode involving an insult, reported levels of anger did not differ between members of honor and dignity cultures (note that none of the episodes included threats to masculine honor; Rodriguez Mosquera et al., 2008). Similarly, Moroccan/Turkish Dutch and ethnic Dutch felt similarly angry when recalling a recent episode involving an insult (Rodriguez Mosquera et al., 2008). In another study, Spanish participants, compared with Dutch participants, reported that they would experience *lower* levels of anger when they were asked to imagine themselves being subjected to insults that were framed as threats to individualism (i.e., portraying them as lacking autonomy and not being assertive in social relations) (Rodriguez Mosquera et al., 2002b). Thus, the pattern of findings observed in cultural comparisons seems to depend on the focus of insults (explicitly honor related or not) or the method used; people from honor and dignity cultures appear more similar than different when they are asked to imagine or recall situations related to insults as opposed to when actual behavioral responses are examined. This might be because individuals selected events that really matter to them in the former case, and events that really matter to individuals may lead to similar emotional–cognitive consequences across different cultural groups.

Shame is another emotion closely related to honor. It is typically experienced in response to moral violations or inferiority (e.g., Tangney & Dearing, 2002), and, important for the current context, in response to threatened social image. Thus, shame is tightly linked to loss of honor (Wikan, 1984; Miller, 1993; Peristiany, 1965). A member of an honor culture is socialized to feel shame when social respect is lost and his or her reputation is damaged, as a result of actions he or she committed, such as

failing to effectively respond to threats (D. Cohen, 2003), or by close others, such as lacking sexual modesty (Rodriguez Mosquera et al., 2002b). Feeling shame in response to loss of honor signals that one is attached to the honor code and highlights concern for external judgment. This way, shame helps solidify a person's identity as someone who is concerned about his or her social image and reinforces social interdependence (Rodriguez Mosquera, Manstead, & Fischer, 2000; Kitayama, Markus, & Matsumoto, 1995). It is expected that both men and women in honor cultures experience shame when honor is damaged, albeit perhaps for different reasons: men for not being able to maintain and protect their family's social image, and women for engaging in actions that could potentially stain personal and family honor.

As with anger, research shows differences between members of honor and dignity cultures in the intensity of shame felt in response to negative honor-relevant events, as well as in how shame is experienced. For example, Spanish participants reported more intense shame in response to threats to family honor in a vignette than did Dutch participants (Rodriguez Mosquera et al., 2002b). An examination of descriptions of typical shame episodes generated by Spanish and Dutch participants showed that descriptions by the Spanish were more other-focused, whereas descriptions by the Dutch were more self-focused; the Spanish also were more concerned with possible negative social implications of shame events than were the Dutch (Fischer et al., 1999). Moreover, Spanish participants expressed their feelings of shame to a greater extent than did Dutch participants (Rodriguez Mosquera et al., 2000). Finally, Spanish cultural prototypes of shame were more available and elaborate than Dutch cultural prototypes of shame (Fischer et al., 1999).

In an investigation of how the experiences of anger and shame may shape motivational and behavioral outcomes among members of honor (Moroccan/Turkish Dutch) and dignity (ethnic Dutch) cultures, Rodriguez Mosquera and colleagues (2008) asked participants to recall and describe a recent episode in which a person insulted them, and to report how they felt about the event and what they did. They found that for members of both types of cultures, feelings of anger predicted wanting to punish the perpetrator; wanting to punish the perpetrator predicted the extent to which participants engaged in verbal attack. By contrast, honor moderated how

feelings of shame shaped motivational and behavioral outcomes. In line with past research on shame in individualistic cultures (e.g., Tangney, Miller, Flicker, & Barlow, 1996), feelings of shame led to withdrawal among low-honor participants, whereas feelings of shame among high-honor participants were associated with a desire to protect their social image, which in turn predicted confronting the perpetrator by expressing verbal disapproval. Moreover, anger and shame were negatively correlated among the low-honor participants, but were positively correlated among high-honor participants. This study demonstrates the different pathways shame can follow in reaction to insults, leading to engagement or disengagement with the perpetrator, depending on the extent to which honor is valued in a given cultural context.

Pride is yet another type of emotion related to honor, but to positive aspects of honor, unlike anger and shame. It is a more complicated emotion compared to anger and shame, with potentially both positive and negative consequences for members of honor cultures when expressed socially. This is because pride can potentially lead to a separation between oneself and others in interdependent honor cultures (Rodriguez Mosquera et al., 2000; Kitayama et al., 1995). Research suggests that pride carries more negative implications in honor cultures (Spain) than in dignity cultures (the Netherlands; Fischer et al., 1999). This finding is corroborated by another study comparing the Dutch and the Spanish, which showed that the Dutch more often reported positive feelings in their descriptions of prideful actions than did the Spanish (Rodriguez Mosquera et al., 2000). Similarly, American participants reported higher levels of positive emotions (including pride) in response to honor-enhancing situations than did Turkish participants (Uskul et al., 2014). As in the shame episodes mentioned earlier, Spanish descriptions of pride episodes tended to be other-focused, whereas descriptions by the Dutch tended to be self-focused (Fischer et al., 1999). Similar to shame, the cultural prototypes of pride were much more available and elaborate among the Spanish compared to the Dutch (Fischer et al., 1999).

In addition to individuals' emotional responses to honor-relevant situations across cultures, research has also investigated how honor is implicated in daily life, as can be observed in the nature of situations typically encountered by members of honor and dignity cultures, and how

these situations may shape individuals' emotional experiences. Uskul and colleagues (2012) found that honor-relevant situations generated by Turkish participants were evaluated as having stronger emotional impact on oneself, one's family members, and one's acquaintances than did those generated by Northern American participants. In a follow-up study, Uskul and colleagues (2014) showed that this was likely due to honor-attacking and honor-enhancing situations generated by Turkish participants eliciting stronger negative and positive emotions, respectively, compared to those generated by Northern American participants. In a similar fashion, Boiger and colleagues (2014) demonstrated that both Turkish and Japanese participants perceived situations with male protagonists generated by Turkish participants to elicit intense levels of anger. An analysis of why Turkish situations might be associated with stronger emotional responses suggested that Turkish situations were more likely to contain emotionally charged extreme behaviors, such as false accusation (Uskul et al., 2014) or intentional harmdoing (Boiger et al., 2014). In a further inspection of situations, Boiger et al. (2014) showed that Turkish participants perceived anger and shame situations to occur more frequently, to the extent that they elicited intense feelings of anger and shame, respectively, and that the affordance of anger and shame was perceived to be more pronounced in interactions with distant than with close others. Moreover, they found that Turkish participants viewed shame to be promoted more in situations that involved a female protagonist. These findings demonstrate the need to go beyond assessments at the individual level when examining honor and emotions, and highlight the power of situations in eliciting emotions in culturally meaningful ways.

Summary

So far, studies have examined primarily anger, shame, and pride in response to honor-related experiences, which has helped us to gain a more comprehensive understanding of negative emotional consequences of honor than positive ones. With a few exceptions, most studies in this domain have made use of scenarios or past episodes of honor events (e.g., insults) and relied heavily on self-reports of emotional responses to these events. The

type of method and insult included in the investigations seem to shape the pattern of cultural differences observed in emotional responses.

CULTURAL TRANSMISSION OF CULTURES OF HONOR

The norms, values, beliefs, and practices brought to the American South by Celts more than 300 years ago would have faded long ago without ecologies, socialization practices, institutions, and structures that maintained and perpetuated them over the generations. First, in the US South, the cultural of honor was most strongly maintained in geographic areas similar to those of the Celt's homelands: regions dominated by herding, scarcity, and little access to the rule of law (Baller et al., 2009; Messner et al., 2005; Nisbett & Cohen, 1996). Parents also pass down these norms and attitudes to their children. D. Cohen and Nisbett (1994) found that people from the U.S. South were more likely than those from the Midwest to endorse statements that reflected a positive attitude toward violence in response to an insult. For example, Southerners were more likely than Midwesterners to say they would encourage a boy who had been bullied to "take a stand and fight the other boy" (p. 560). Southerners were also more likely than Midwesterners to endorse spanking as a means of disciplining a child. Although much of the research on honor in the Southern U.S. has focused on masculine honor and men's behavior, women play important roles in the maintenance and perpetuation of a culture of honor through enforcing it on their menfolk, socialization of honor norms in their children, and sometimes participating in its behavioral patterns too (Nisbett & Cohen, 1996; Vandello, Cohen, & Ransom, 2008).

Culture of honor practices and preferences play out in social institutions as well, such as local schools. One of us (Cross), a native of the U.S. South, recalls the wooden paddle that hung prominently in the high school principal's office as a warning to troublemakers. As of 1997, public, state-supported schools in the U.S. South were more likely than those in the U.S. Northeast to allow physical punishment of students for infractions (Arcus, 2002); rates of physical punishment were also higher in Southern states than in other states (D. Cohen, 1996). Notably, the rates of fatal shootings in

schools between 1992 and 1999 were highest in states where corporal punishment was permitted (controlling for other, related factors such as poverty and religion; Arcus, 2002; see also Brown et al., 2009). School shootings (almost entirely committed by males) often occur in response to bullying, taunts, or ostracism by others (Leary, Kowalski, Smith, & Phillips, 2003; Newman, Fox, Roth, Mehta, & Harding, 2005); thus, bullied children reared in cultures of honor may feel impelled to retaliate with violence.

Legal systems both reflect and maintain a society's key values and ideals, and those in cultures of honor may legitimize violence for defense of honor, self-defense, or retaliation for certain offenses. As mentioned earlier, the Southern and Western regions of the United States have fewer gun control laws, and more laws that permit aggressive defense of self and home, and that allow the state to execute prisoners (D. Cohen, 1996). Legal systems in honor cultures also tend to apply less harsh punishment to instances of aggressive retaliation against threats to honor compared to those in dignity cultures. In some Middle Eastern countries, the law specifically takes account of provoked husbands in the case of honor crimes and extends more lenient punishments compared to other, similar crimes (e.g., Abu-Odeh, 1996). A survey of honor crimes in 14 countries conducted by the International Women's Human Rights Clinic (2000) revealed that judges in many of the countries tended to be lenient toward male offenders; in this way, the judiciary sends "a powerful signal to the community that the State will allow this practice to continue" (p. 4, quoted in Torry, 2001, p. 319).

A comprehensive study of transmission of cultural practices involves not only asking *how* the transmission takes place but also *why* it takes place. To understand the conditions under which honor cultures evolve, and why and when honor cultures might be adaptive, Nowak, Gelfand, Borkowski, Cohen, and Hernandez (2016) carried out an agent-based model of honor. Their findings highlighted the need to consider the strength of institutions and toughness of the environment, as well as the interactions between different subcultures of a society in order to reach a comprehensive understanding of the evolutionary basis of honor cultures. This study shows that honor cultures may be adaptive and functional under certain conditions (i.e., when institutions are weak), because honor cultures can control the spread of aggressive behavior, which suggests that short-term irrationality often associated with honor cultures has to be evaluated within the context

of a long-term strategy (see Leung & Cohen, 2011). In a theoretical analysis of why honor concepts are culturally transmitted and preserved, Nordin (2013) suggests that certain cognitive systems referring to male formidability, management of reputation, coalitions, costly signals, shame and stigma, and concerns for protectiveness and parental investment underpin the cultural selection of honor concepts.

In summary, ecological conditions, socialization patterns, school policies, and legal practices are just a few of the structures that uphold and transmit culturally specific norms and values to new generations. This review is necessarily brief, but the existing empirical research is also relatively sparse, particularly outside the United States. Further research that specifically examines how concerns for honor are reflected in cultural products designed for children (e.g., children's books; Tsai, Louie, Chen, & Uchida, 2007; Tsai & Clobert, [Chapter 11](#), this volume) or that empirically examines other cultural products (e.g., laws, social policies, or other institutional practices) is needed to facilitate a better understanding of how cultures of honor may persist or change over time.

OBSERVATIONS AND FUTURE DIRECTIONS

General Observations

Our review of the social-psychological literature on honor has yielded six general observations. First, research on honor has so far focused predominantly on comparisons between people in the Southern/Western and Northern United States, representing honor and dignity states, respectively, and between Western dignity cultures (e.g., the Netherlands) and Southern and Southeastern European honor cultures (e.g., Spain, Turkey). Honor cultures in different parts of the world, such as South Asia, South America, and the Middle East and other parts of Europe, have received less attention. Our understanding of honor and its psychological consequences would benefit from a wider coverage of honor cultures and their comparison with different nonhonor cultures (i.e., not only different dignity cultures but also face cultures). The literature would also benefit from more regional or group-based analyses of honor within countries other

than the United States (e.g., west vs. north Turkey; Muslim vs. non-Muslim regions in India; Muslim immigrants within a Christian host society), if theoretical reasons render such comparisons meaningful, as well as more comparisons between different honor cultures (e.g., Southern United States vs. Turkey). Such comparisons will help researchers examine whether there are different forms of honor cultures (just as there are different types of individualistic or collectivistic cultures) by allowing us to discover the diverse ways in which honor may be conceptualized and lived by different groups. They would also help researchers discover alternative reasons why cultures of honor emerge or alternative mechanisms through which they are maintained. Overall, greater diversity in terms of samples and comparisons will help us move away from (implicitly) treating all honor cultures uniformly.

Second, research so far has concentrated on the negative consequences of honor or what happens when honor is lost in general and the honor-aggression link in the interpersonal domain in particular. Positive or non-aggression-related consequences of honor, or what happens when honor is gained, have received relatively less attention. We suggest that a greater focus on honor as virtue and its positive consequences, as well as what happens when honor is enhanced, would help us understand honor in more complex ways compared to the more common pejorative lay understanding in the West (that honor leads to destructive behavior).

Third, most available evidence on cultures of honor comes from research conducted with adults. Our understanding of cross-cultural similarities and differences in what honor means and how it operates among children, and the ways in which children acquire and sustain honor codes is limited. More research in this area, including research using longitudinal methods, would shed light on developmental dynamics and cultural transmission of honor codes.

Fourth, while there is ample research to demonstrate differences between regions or cultures in honor-related cognitive, affective, or behavioral outcomes, we still know little about the mechanisms that underpin these differences. Some mechanisms that have been put forward as promising candidates to understand why these cultural differences exist include differences in prevalent motivational orientations between honor and dignity cultures (e.g., prevention vs. promotion focus; Shafa et al., 2015),

and perception of social norms surrounding how one ought to respond to honor-threatening offenses (Cross et al., 2014; Vandello et al., 2008). There are likely other cognitive, affective, and motivational processes that can help explain these differences.

Fifth, recent literature has started making finer conceptual distinctions in the study of honor. For example, some researchers have studied personal endorsements of honor (in the form of subjective commitments) and individuals' perceptions of public norms surrounding honor-related expectations (Cohen & Vandello, 2001) and how these may differ in their relative predictive power for different outcome variables (Cross et al., 2013). Other researchers have distinguished between the meaning and the importance of honor (Helkama et al., 2013). More conceptual refinements such as these will contribute to the field's further theoretical development.

Finally, we find that researchers increasingly focus on feelings of honor originating from different group memberships (national, ethnic, or religious groups). This emerging trend is also mirrored in the growing interest in exploring how honor relates to collective outcomes such as heightened vigilance to threats at the group level (e.g., Barnes et al., 2012a, 2012b, 2014; Dafoe & Caughney, 2016; Levin et al., 2015). It is likely that culture of honor research will continue expanding to other domains, and we foresee that this expansion will integrate honor research to a greater extent into other subfields of psychology (e.g., self-regulation, intergroup violence) and in relevant research in other social science disciplines (political psychology, economics). This is indeed an emerging trend in the literature. For example, although historians, sociologists, and criminologists have traditionally been interested in questions related to cultures of honor and violence (e.g., Altheimer, 2012; Baxter & Margavio, 2000, 2011; Messner et al., 2005; Wyatt-Brown, 2001), recent trends suggest that there is growing interest in economics (e.g., Brooks, Hoff, & Pandey, 2013, 2015), organizational science (e.g., Aslani, Brett, Ramirez-Marin, Tinsley, & Weingart, 2011; Aslani et al., 2016; Gelfand et al., 2015), philosophy (e.g., Sommers, 2009), and political science (e.g., Pely, 2011) in questions related to cultures of honor inspired by existing psychological research in this field.

Future Directions

In addition to general observations based on the current state of evidence, we have also identified areas for future research that could make important theoretical contributions to the literature on honor. One question that, in our view, needs further elaboration is the relative importance of different components of honor in different regions of the world and in relation to different outcomes. For example, although the concept of honor is strongly linked to masculine honor in Latin American countries (e.g., Vandello et al., 2009), in Mediterranean regions and Middle Eastern and Arab societies, what seems to be more at stake is mainly family honor (e.g., van Osch et al., 2013). What aspects of these cultures drive one component of honor to be more important than another component of honor? Moreover, different components of honor can have a different relation to the same outcome within a single cultural group; for example, integrity correlates with higher levels of self-esteem, but family honor correlates with lower levels of self-esteem in a Turkish sample (e.g., Novin, Tatar, & Krabbendam, 2015). What makes these different components of honor operate differently in relation to the same psychological outcomes?

A further interesting question related to this point concerns what constitutes an honor threat in different cultures. In a study on construals of aggression in Japan, Pakistan, Israel, and the United States, Severance and colleagues (2013) found that behaviors targeting one's reputation and social standing (e.g., being socially excluded, gossiped about) were seen as particularly damaging to self-worth in Israel and Pakistan, but not so much in the United States. Similarly, Uskul et al. (2012) found that when asked what constitutes an effective threat to one's honor, Turkish participants frequently mentioned being falsely accused for acts one has not committed or being subjected to unfair treatment, whereas U.S. Northerners frequently mentioned attacks on one's ideas or character features. In a single culture study with a sample consisting mostly of Hispanic or Latino participants, Benavidez, Neria, and Jones (2016) found that participants with high levels of honor endorsement and closeness to a target showed the highest levels of (self-reported) aggressiveness toward a hypothetical honor code violation by that target. As these findings demonstrate, the actions that are considered to threaten honor may take different forms; a more complete understanding of this variation would help researchers understand why members of some

cultures at times respond aggressively to acts that members of other cultures might feel comfortable ignoring.

A further question that would benefit from additional refinement is the public versus private component of honor. Although “the public eye,” or how others evaluate us, is defined as a core component of honor (e.g., Pitt-Rivers, 1965), so far, research has not always shown the expected differences between private and public situations in honor-related outcomes (e.g., D. Cohen et al., 1996; Uskul et al., 2015). This might have been due to public situations in experimental research typically involving an unknown adult or unfamiliar audience. More research is needed that operationalizes “public” as the presence of close others (rather than strangers). Research also needs to expand into the study of honor in public spaces that do not involve face-to-face interactions. Recent studies have begun to capture how surveillance and impression management experiences in social media might differ between honor (Turkey, Azerbaijan) and dignity cultures (e.g., Günsoy, Cross, Saribay, Olcaysoy-Ökten, & Kurutaş, 2015; Pearce & Vitak, 2015).

Finally, research on gender differences in honor endorsement and related outcomes has been less systematic than needed. This is partly due to a significant number of studies in the past focusing on masculine honor and its psychological consequences among men only. This is changing, however, with female participants more regularly included in study samples, but still gender rarely constitutes the focus of studies; it usually is an add-on variable in reported analyses. For example, a recent study on predictors of honor beliefs in a Turkish sample demonstrated that benevolent sexism predicted honor beliefs for women but not for men, and hostile sexism predicted honor beliefs for men but not for women (Glick et al., 2016). This points out the need for further research to highlight gender-specific underpinnings of honor beliefs and concerns (see also Barnes et al., 2012a). More culture comparative and within-culture research on how men and women respond similarly or differently to positive and negative honor-relevant events, as well as research on when in the life course gender differences start emerging, would help us better understand the gendered aspects of honor, including honor-related violence.

In summary, expanding current research to different national, ethnic, and religious samples in various life stages, and to diverse types of honor losses and gains in different life domains will help broaden our

understanding of honor and its relation to other social psychological concepts cross-culturally.

Methodological Considerations

Psychological studies of honor have employed a wide variety of methods, ranging from laboratory research to field observations, and they have assessed a variety of outcome variables. Overall, with some exceptions, our review shows that most studies have used methods that include scenarios depicting honor-relevant events in which participants are asked to imagine that event or to recall an honor-relevant situation that they personally experienced in the past. In terms of outcome variables, again, with some exceptions, most studies rely on the measurement of self-reported emotions or evaluations and intentions to engage in behaviors rather than the observation of actual behaviors. All existing studies provide worthwhile evidence in this relatively new and growing area of research. We would like to highlight, however, that the type of method employed or the nature of the actual outcome measured seems to make a difference in whether similarities or differences emerge in cross-cultural comparisons. For example, we see more similarities than differences between cultural groups when individuals are asked to recall a behavior they experienced in the past that fits a certain criterion compared to when they experience a situation under controlled laboratory settings (e.g., D. Cohen et al., 1996; Uskul et al., 2015). Likewise, we see more similarities across cultural groups when emotional consequences or appraisals are examined than when behavioral intentions, actual behaviors, or even physiology are the focus of investigation. Thus, it seems important to keep in mind the methodology employed and the outcome measures assessed in individual studies when drawing conclusions about cross-cultural similarities or differences.

Our review also has revealed a shift in the psychological literature on honor from almost exclusively comparative research that focused on exploring (cultural or regional) differences between honor and dignity cultures in the 1990s to research that approaches honor endorsement as an individual-difference variable. Indeed, the last two decades have witnessed the development of different measures of individual differences in honor

endorsement at the explicit (Barnes et al., 2012a; Figueredo, Tal, McNeil, & Guillén, 2004; Guerra, Gouveia, Araújo, Andrade, & Gaudêncio, 2013; IJzerman et al., 2007; Rodriguez Mosquera et al., 2002b; Saucier & McManus, 2014; Saucier et al., 2016; Somech, & Elizur, 2009; Vandello et al., 2009; for the measurement of endorsement of honor-related violence see Leung & Cohen, 2011) and implicit levels (Imura et al., 2014). These measures focus on different aspects of honor beliefs, values, or ideologies (e.g., masculine honor, family honor, chastity). The coverage of the literature on individual differences in honor endorsement is beyond the focus of this chapter, unfortunately. Although the contribution of the individual-differences approach to honor might be limited in terms of our understanding of cultures of honor, we do recognize that it allows researchers to investigate honor within a single culture or region, and investigate its relations with other social psychological constructs with greater precision. The research literature also shows signs of growing interest in finding ways of manipulating honor by making salient its different components and testing how these impact different psychological processes (Leung & Cohen, 2011; Shafa et al., 2015), as well as how honor is embodied (IJzerman & Cohen, 2011).

Overall, these are exciting times for research on cultures of honor. The growing corpus of research on cultures of honor shows that this framework has been useful in understanding cultures not typically included in the traditional East–West comparisons that have been studied for decades. It has also helped researchers go beyond the commonly employed individualism–collectivism cultural dimension and start unfolding different types of collectivism that might exist. With its increasingly diverse methodological toolkit and expansion to different life domains beyond interpersonal aggression, culture of honor is also a promising cultural syndrome that can be a meaningful framework for researchers in other disciplines who are interested in understanding human behavior cross-culturally.

CHAPTER 31

Transnational Terrorism, Devoted Actors, and the Vitality of Cultures

Scott Atran

Homo sum: humani nil a me alienum puto.

(I am human, I consider nothing human alien to me.)

—TERENCE, *Heauton Timorumenos* (*The Self-Tormentor*), Act I, Scene 1

This chapter addresses transnational terrorism in three parts: examination of critical problems with prevailing frameworks for understanding in the security and academic communities, theoretical arguments and empirical evidence for value-driven versus utilitarian motivations for extreme violence, and analysis of the emergence of globalization's "dark side" as a world-historic phenomenon favoring radical politics and action. The first part reveals that despite intense efforts by intelligence agencies and countless academic conferences, articles, and books, fundamental aspects of terrorism remain unclear—for example, how people radicalize, what motivates their violence, and what countermeasures are most effective. The second part provides empirical findings with fighters in Iraq on the frontline of the Islamic State (ISIL, ISIS). Combined with results from multiple online studies, this evidence addresses willingness to fight and die in intergroup conflict. The focus is on nonutilitarian aspects of human conflict, which combatants themselves deem "sacred" or "spiritual," whether secular or religious. The third part examines historical and geopolitical conditions favoring the eruption of *jihadi* and far-right movements, which

threaten open and democratic societies in ways somewhat similar to how fascists and communists worked in tandem in the 1920s and 1930s.

BRINGING THE TERRORIST THREAT DOWN TO EARTH

The 9/11 attacks cost al-Qaeda \$400,000–500,000 (National Commission on Terrorist Attacks upon the United States, 2004), whereas the United States Government (USG) has likely spent \$4–5 trillion or more in the “War on Terror” in the years since (Watson Institute, 2016). Despite this investment, the global threat arguably has not abated. In just 2 years, the Islamic State (ISIS or ISISL) created the largest foreign volunteer force since World War II, drawing fighters from the majority of the world’s nations, and inspiring attacks that have killed or wounded thousands across the globe (Allison, 2016).¹ Overwhelming military force by a large coalition of nations will likely destroy the Islamic State’s territorial base in the Middle East, but inasmuch as the Islamic State is more a symptom than cause of political fragmentation and social turmoil in the Sunni Arab world and beyond, that is unlikely to end the *jihadi* threat.

Nevertheless, the war-fighting capabilities of ISIS and al-Qaeda combined do not even approach, say, the manpower and firepower of the Belgian army alone. Perhaps never before in history have so few, armed with such relatively few material means, frightened so many across the planet. The shutdown of Brussels in the wake of the Paris attacks, or of Boston in the aftermath of the marathon bombings in 2013, speaks to a comparable fear, and contributes to an underlying lack of faith in our own societies and values, something that terror attacks are designed to promote. During World War II, not even the full might of the German Luftwaffe at the height of the Blitz could compel the British government and the people of London to cower so. Today, mere mention of an attack on New York in an ISIS video has U.S. officials scurrying to calm the public. A rumor that someone heard a cry in Arabic of *Allahu Akbar*, “God is Great,” in a shooting or a stabbing—ignoring the many thousands of more lethal or damaging events—is often enough for the major news services to post breathless alerts for “Breaking News.” Media exposure, the oxygen of terror in our age, not only amplifies

the perception of danger but, in generating such hysteria, makes the bloated threat to society real.

This is especially true today, because the media are mostly designed to titillate the public rather than inform. Thus, it has become child's play for ISIS to turn our own propaganda machine, the world's mightiest, into theirs—boosting a novel, highly potent jujitsu style of asymmetric warfare that we *could* counter with responsible restraint and straight-up information.

The outcome is preposterous and dangerous. The U.S. Justice Department, with overwhelming support from Congress and the media, now considers the common kitchen pressure cooker to be a “weapon of mass destruction” if used for terrorism. This ludicrously levels a cooking pot on par with a thermonuclear bomb that has many billions of times greater destructive power. It trivializes true weapons of mass destruction, making their acceptance more palatable and their use more conceivable. In this present hyperreality, messaging is war by other means. ISIS's manipulation of our media has created a sense of foreboding of mass destruction where it isn't really possible, at the same time obscuring greater real threats: even with ISIS driven from its territorial centers in Raqqa and Mosul, the specter of ISIS has loomed much greater in the popular press or in political discourse than the far greater menace of nuclear holocaust.

Failure to find consensus on social and behavioral aspects of terrorism starkly contrasts with progress in understanding some of the weapons terrorists might choose. Natural scientists and engineers have learned much about mitigating possible chemical, biological, radiological, nuclear, and high-yield explosive (CBRNE) threats from substate and transstate groups. They have benefited from receiving a significant portion of nearly \$3 billion that the U.S. Department of Defense (DoD) spends annually on CBRNE (Global Biodefense, 2016). They have also benefited from sustained interaction with personnel in the field and access to classified data.² Appropriate financial and collaborative conditions have not addressed the social and political dynamics driving use of these threats, much less the likelier menace of mass shootings or stabbings, rampaging vehicles, or explosions of airplanes. But perhaps a greater reason for limited progress in understanding transnational terrorism in order to deal with it effectively relates to conceptual and empirical challenges.

As we shall see, addressing these problems requires, at a minimum, tighter conceptual framing of “terrorism,” grounding analysis in scientifically collected and interpreted field research with actual terrorists and the conditions in which they operate. But perhaps the deepest problem concerns the conceptual framework that our society and political culture use to understand human nature in its dealings with transnational terrorism.

In our preferred world of liberal democracy and human rights, violence—especially extreme forms of mass bloodshed—are generally considered pathological or evil expressions of human nature gone awry, or collateral damage as the unintended consequence of righteous intentions. But across most human history and cultures, violence against other groups is universally claimed by the perpetrators to be a sublime matter of moral virtue (Fiske & Rai, 2014). For without a claim to virtue, it is difficult, if not inconceivable, to kill large numbers of people who are innocent of direct harm to others. Besides, brutal terror scares the hell out of enemies and fence sitters—let us not forget the rationale for nuclear carnage at Hiroshima (Lifton & Markusen, 1990).

On one side, we have a culture that has built an awesome military capability to defeat or neutralize any other state’s military threat, but whose key decision makers (as well as many others) have a fairly narrow view of human motivation and action. That analytic framework for interpreting human behavior is based mainly on utilitarian (cost–benefit) presumptions about “rational actors.” Rational actor theories generally assume that individuals select among available preferences (depending on potential costs and benefits in determining those preferences with the information at hand) to act in ways consistent with chosen preferences and the likelihood of outcomes expected from such action. If people fail to meet such “rational” expectations, then they are considered “irrational,” unless their behavior also can be explained as bounded by cognitive processing limitations (Simon, 1997), lack of cultural awareness (Schelling, 1960), intrinsic indivisibility of resources (Fearon, 1995), or other biases and ecological constraints (Kahneman, 2011).

Political reactions to transnational terrorism therefore alternate between trying to find the material, self-interested motivation driving terrorists’ behavior and viewing them as crazy. We expend enormous resources to find technological solutions to problems of transnational terrorism (e.g., through

detection of IEDs and possible chemical, biological and nuclear weapons, or trying to use supercomputers to find a needle in a haystack); however, there is relatively scant attention to terrorists' actual motivation or psychology, few resources committed to studying people in the field, and comparatively little intimate and sustained engagement with the personal networks off which terrorist groups feed, wherein may reside the most useful information for preventing violence. In short, the focus is on rational deterrence, a strategy more applicable to state-on-state power rivalries than to conflict in which opponents are non-state actors fighting for a sacred cause. Decision making is hierarchic and bureaucratic, and funding for counterterrorism is politicized and required to produce short-term, quantifiable results.

On the other side, transnational terrorist groups are often only loosely hierarchical, horizontally intricate and based in personal networks, and nimble. This side focuses less on mass messaging "ideology" or "narratives" to a general audience, and more on personal engagement with the aspirations and grievances circulating in particular kinship and friendship networks. The bonds created within a militant group are of imagined kinship—brotherhoods, motherlands, and the like. The overall conceptual framework views good people as righteous and spiritually motivated, and enemies as moral nihilists lacking in spiritual strength. The focus of action is on the long term rather than here and now: "You've got the watches but we've got the time" (Pressfield, 2011).³

With transnational terrorism, as with other violent expressions of seemingly intractable conflict—with Israelis and Palestinians (Atran & Ginges, 2009), Saudis and Iranians (Dehghani et al., 2009), blood feuds in southern Europe or the U.S. South (Nisbett & Cohen, 1996)—ample historical and cross-cultural evidence shows that perceived insults to faith, dignity, honor or, generally, one side's failure to show respect to the other side's cherished values can lead to intergroup violence that may persist for decades, even centuries. Disputes over otherwise mundane phenomena (people, places, objects, events) then become existential struggles, immune to the utilitarian logic of risks and rewards, costs and consequences (Atran & Ginges, 2012).

In this regard, a utilitarian and instrumental approach to transnational terrorism may be insufficient to explain, predict, or parry willingness to fight and die for a cause if such willingness is shaped by duty-bound devotion to

sacred values and identity groups with which people are fused, as, for example, with some suicide bombers (B. Hoffman & McCormick, 2004). “Sacred values” are preferences, beliefs, and practices that communities deem protected from monetary or other material trade-offs, such as when land or law becomes holy or hallowed. Within this framework, people most willingly engage in costly sacrifices and extreme actions when motivated to protect non-negotiable sacred values (Tetlock, 2003; Ginges, Atran, Medin, & Shikaki, 2007)—whether religious (e.g., holy law) or secular (e.g., democracy)—and such values are associated with a group with which they feel viscerally connected and that imbues members with a collective sense of invulnerability (Swann, Seyle, Gómez, Morales, & Huici, 2009; Gómez et al., 2011). Ever since World War II, on average, revolutionaries and insurgents willing to sacrifice for their cause and group have prevailed with up to 10 times less firepower and manpower than the state armies and police forces (which rely mainly on material incentives and disincentives such as pay, promotion, and punishment; Arreguín-Toft, 2001).

* * *

Terence, the Roman slave who became a playwright, gave the field of anthropology an enduring credo: to empathize with those most different from one’s own moral culture, without necessarily sympathizing. This is our call to comprehend. If we can only grasp why otherwise normal humans would want to die killing masses of other humans who have not directly harmed or meant to harm anyone, we might ourselves better avoid killing and being killed.

In what follows, I intend to illustrate a dynamic interdisciplinary collaboration between (1) in-depth anthropological fieldwork with groups of people apt to act against other groups with extreme violence, in order to elicit possible patterns of thought and behavior different from what we may expect from our own society and cultural biases, and (2) rigorous psychological experimentation to see whether those patterns hold and whether they can be generalized to different cultural contexts and populations. Although I and my colleagues at *Artis International*—an academic and policy group that focuses on field-based scientific research to lessen intergroup violence around the world⁴—consider that the testing of hypotheses and the evaluation of evidence must be wholly independent of

policy priorities and concerns, we also hold that policies affecting the security of the lives of our citizenry and others are better informed than not by scientific evidence (Atran, Axelrod, Davis, & Fischhoff, 2017).

To highlight the relevance of the sort of data collection and hypothesis testing to be illustrated (comprising the second part of the chapter), it is wedged below between a preliminary discussion and critique of post-9/11 policy and academic research on terrorism (the first part), and a concluding discussion of the world-historical context within which transnational terrorism has arisen that suggests the threat to our way of life not only comes from “them” but from within “us” (the third part).

A CRITICAL OVERVIEW OF POST-9/11 POLICY AND RESEARCH ON TERRORISM

Transnational Terrorism: Narrowing the Scope of Inquiry to Something Tractable

There are significant differences between terrorist groups in terms of organizational structure (e.g., top-down hierarchies, acephalous networks), motivating beliefs (e.g., secular, religious), ultimate goals (e.g., single issue change, wholesale societal transformation), operational scope (e.g., local, regional and beyond), type of personnel (e.g., volunteers, draftees), populations for support and recruitment (e.g., marginal, mainstream), and so forth. There are also considerable differences within terrorist groups and across time: for example, many of al-Qaeda’s founders and international operatives came from backgrounds of relatively high education and socioeconomic status, including both religious and technical education (e.g., medicine, engineering), whereas later adherents mostly came from backgrounds of lower socio-economic status and less education—a difference also evident in ISIS today between midlevel foreign volunteers and operatives versus foot soldiers, both foreign and local.

Yet even these narrow generalizations need hedging for effective policy. Thus, ISIS has tended to recruit from among Muslim underclass of North African origin across Western Europe, but much less so from Muslim underclass of Turkish and Pakistani origin, and also more so from middle-

class Muslims in British universities and higher academic echelons of North African universities. This makes broad socioeconomic portrayal problematic even of an “ISIS terrorist” or “foreign volunteer.” Nevertheless, through repeated actions, rhetoric and policies by certain violent groups and by governments and international bodies (United Nations [UN], Interpol, etc.) that oppose them, there appears to be some consensus that transnational terrorism is a strategy (1) by groups that are bound together by ideological affiliation but not by internationally recognized structures of existing nation-states (2) to effect long-term societal change across nations in conformity with political or religious doctrine (3) by persistent means of extreme violence against nonconforming civilian populations in order to destabilize and undermine their prevailing order, (4) while increasing conformity and support among civilian populations susceptible to alienation from, and hostility to, the prevailing order. The prevailing form of transnational terrorism that currently agitates the world and drives counterterrorism policy incorporates radical Islamist views (waging war against non-Muslim civilian populations, excommunication, and allowed killing of nonconforming Muslims, elimination of the “gray zone” between believers and nonbelievers, eventual world domination by true believers, etc.).

For example, the following are axioms drawn from *The Management of Chaos-Savagery (Idarat at-Tawahoush)* (Naji, 2006), required reading for every ISIS political, religious, and military leader, or *amir*), and from the February 2015 editorial in *Dabiq* (online ISIS publication), on “The Extinction of the Gray Zone” (Middle East Media Research Institute [MEMRI], 2015). ISIS’s actions have been, and those of its acolytes and successors likely will continue to be, consistent with these axioms:

- Work to expose the weakness of the so-called “Great Powers” by pushing them to abandon the media psychological war and war by proxy until they fight directly.
- Draw these powers into military conflict. Seek the confrontations that will bring them to fight in our regions on our terms.
- Diversify the strikes and attack soft targets—tourist areas, eating places, places of entertainment, sports events, and so forth—that cannot possibly be defended everywhere. Disperse the infidels’ resources and drain them

to the greatest extent possible, and so undermine people's faith in the ability of their governments to provide security, the most basic of all state functions.

- Target the young, and especially the disaffected, who tend to rebel against authority, are eager for self-sacrifice, and are filled with idealism; and let inert organizations and their leaders foolishly preach moderation.
- Motivate the masses to fly to regions that we manage, by eliminating the "Gray Zone" between the true believer and the infidel, which most people, including most Muslims, currently inhabit. Use so-called "terror attacks" to help Muslims realize that non-Muslims hate Islam and want to harm all who practice it, to show that peacefulness gains Muslims nothing but pain.
- Use social media to inspire sympathizers abroad to violence. Communicate the message: Do what you can, with whatever you have, wherever you are, whenever possible.
- Pay attention to what works to hold the interest of people, especially youth, in the lands of the Infidel [e.g., television ratings, box office receipts, music and video charts], and use what works as templates to carry our righteous messages and calls to action under the black banner [of the Islamic State].

Note that populations targeted by transnational terrorism are understood to be overwhelmingly noncombatant, and susceptible supporting populations are overwhelmingly noncriminal. Under this characterization there really are no "lone-wolf" transnational terrorists, because every individual actor belongs to an active ideological group, even if only through virtual means (e.g., social media); and there is no transnational state terrorism, although some internationally recognized states do occasionally target select foreign civilian populations, and some states support terrorist groups. Even given this restricted characterization of transnational terrorism, any serious study should specify which specific terrorist groups are involved, under what criteria they may be systematically compared and contrasted, including what distinct structural roles individuals may play within and across these groups (Koehler-Derrick, Pedhazur, & Perliger, 2016). If it turns out that there are broader and more detailed commonalities that may be systematically captured in ways that make identifying terrorists and anticipating terrorist acts more tractable and

predictable, then that would be a significant result of scientific inquiry rather than an ad hoc condition for it.

Limits of Prior Frames from Foreign Policy, Military Doctrine, and Criminal Justice

Immediately after 9/11, the USG relied almost exclusively on the intelligence community, which monitors individuals and groups that threaten national security, and specializes in clandestinely gathering and analyzing pertinent information. Critical problems associated with data collection and interpretation limited this effort to understand terrorist groups in terms of motivations, recruitment, and capabilities. The intelligence community had nearly all of the existing data on actual, possible, and potential terrorists; however, such information was not necessarily constrained by scientifically testable theories and methods or systematically cross-examined for accuracy and completeness. Case officers placed into specific countries often could not directly verify information in the field, because protocol prohibited them from engaging directly with local communities rather than through local authorities and informants. Of course, the pressing need to protect people's lives and assets justified use of partial information, sometimes to good effect, in capturing dangerous terrorists and preventing terrorist actions; but policymakers tended to fit such information to prevailing paradigms—in (1) foreign policy, (2) military doctrine, and (3) criminal justice, each with serious drawbacks when applied to terrorism.

Foreign Policy

The USG national security structure is primarily built to manage state-to-state interactions. Emergence of substate and transstate threats, such as al-Qaeda and now Islamic State (which considers itself a global archipelago), challenges a structure tethered to country and regional desks that tends to impute well-known forms of state-organized and state-sponsored violence (hierarchical command and control, well-formed cells, direct recruitment, etc.) to terror groups with more diffuse and fluid spatiotemporal

organization and operational management (Sageman, 2008). For example, hierarchical command and control implies that a “decapitation strategy” to eliminate terrorist leaders might best end the scourge, which the U.S. administration initially adopted. In time, however, key USG officials involved in combating terrorism found that “decapitation” produced “diminishing returns” in “thwarting of new recruits” for al-Qaeda and its ilk (Gellman & Linzer, 2004), even though extensive leadership removal through elimination or apprehension has shown a significant reduction in suicide attacks and other forms of extreme violence among groups in more constrained theaters of operation, such as the Israel–Palestine conflict after early 2004.⁵

Failure to conceptually decouple transnational terrorism from state-sponsored violence also facilitated belief that ties between the Iraq regime and al-Qaeda were stronger than they were, threatening the United States and allies with imminent state-sponsored terrorism. This coupling of separate issues contributed to the justification for the 2003 invasion of Iraq (Cincinnati Museum Center, 2002).⁶

Military Doctrine

U.S. war fighting doctrine relies on “cost imposition” as key to any strategy to defeat an enemy, including terrorism and terrorists: “In confronting the range of security challenges it will face in the 21st century, the United States must constantly strive to minimize its own costs in terms of lives and treasure, while imposing unsustainable costs on its adversaries” (DoD, 2006, 2014, 2015). Yet suicide bombers, for example, do not seem to respond to utilitarian cost–benefit strategies. Rather they often appear to follow moral (deontic) reasoning, willing to sacrifice for a cause no matter the cost. Instrumental calculations focus on publicizing each death to inspire more young Muslims to join the cause. Indeed, utilitarian perspectives (offers of jobs, housing, money) often play into the hands of some terrorists, who point out that the United States and allies try to reduce people to material things rather than moral beings.

A general belief that terrorism will stop if made too costly to resist, through either force advantage or better material offers, underestimates the

revolutionary zeal and capacity of some truly devoted actors and can lead to great loss in treasure and lives. Thus, during the Iraqi surge of U.S. troops in 2007–2008, ISIS (established in 2006, before it became the Islamic State Caliphate) lost nearly all territory, up to three-fourths of its foot soldiers, and about a dozen high-value targets for each of 15 consecutive months (Johnston et al., 2016). Although no longer considered a viable force by the USG, it was able to take advantage of security vacuums offered by Syria's civil war and U.S. troop withdrawal from Iraq, gain the local Arab Sunni population's support as "The Revolution" (*al-Thawra*), launch a Caliphate drawing volunteers from across the world and, in a brief time, reign over hundreds of thousands of square kilometers and millions of people. Overwhelming military force by a large coalition of nations will likely destroy its current incarnation as Islamic State, but it could be a grave mistake to again underestimate the ideological and moral force, linked to emotions associated with perceived injustice (McCauley, 2016), and perhaps their uptake by a resurgent al-Qaeda in the Levant.

Criminal Justice

Following 9/11, the USG adopted a criminal justice framework at home, seeking to prevent terror through "deterrence, disruption, and interdiction," supported by military interventions abroad. Military intervention largely dealt with late developments, after terrorists and terrorist events had already erupted. Criminal investigation techniques develop evidence to support criminal charges in court against terrorists, which is vital for dealing with actual or incipient terrorist events (White House, 2002). Preventing terrorism, however, requires additional perspectives. Unlike terrorism, most criminal activity does not involve low-probability, high-impact events, deliberate targeting of many anonymous civilians, and active support and recruitment from noncriminal populations. Moreover, whereas criminology has developed somewhat reliable checklists, preincident indicators, and profiles for specific forms of criminal activity and their perpetrators (e.g., securities fraud, serial killers), little evidence approaching statistical or clinical reliability exists for terrorism or terrorists. In part this is because a criminal view of terrorist violence is too broad (secular, religious, local,

transnational, etc.), in part because available information often is incomplete, unverified, or unverifiable.

Take, for example, Britain's guidance for Identifying Vulnerable Persons (IVP), currently the only screening tool for violent extremism in the public domain that allows scientific scrutiny. Although IVP (and other checklist-based instruments) prove useful in assessing mentally disordered and criminal offenders, integrity and completeness of information are lacking when applied to prospects of extreme violence. Screening tests involving brief measures generate "false positives" (e.g., misjudging people as terrorists) and "false negatives" (e.g., failure to identify individuals beginning to engage with violent extremism). Moreover, "using unreliable outcomes uncritically underlines the importance of any screening being supplemented by specific intelligence (akin to clinical information) regarding the person of interest and does not supercede human-led risk assessment of the case and acute risk states" (Egan et al., 2016). Problems of checklists for identifying terrorists are mirrored by preincident indicators for terrorist acts, which determine preventive countermeasures that can greatly affect citizens' lives and rights (Haverkamp, 2014).

In short, when the base rate for terrorist acts and terrorists is negligible in the resident population (as in the European Union [EU] and even more so in the United States), and the focus is on indicators of criminal activity rather than systematic signs and stages of radicalization based on experience with an array of actual *jihadis* and the contexts in which they arise and operate, then there is high risk for false positives and negatives that increase fear and suspicion among minority and majority populations and actually enhance recruitment, undermine faith in the security system, and jeopardize basic rights (Doosje, Moghaddam, Kruglanski, & Rienk Feddes, 2016). At a minimum, one might recommend a more narrow focus on ideologically motivated violent extremists, informed by case-based human intelligence from the field to improve reliability.

Limits in the Initial Involvement of the Academic and Scientific Research Community

With increasing awareness of problems associated with classified data collection and validation, a state-centered and top-down focus on interpretation, and a military and criminological approach to identifying terrorists and anticipating terrorists acts, some in the White House, including members-to-be of our research team, turned to the academic community for help, and Congress budgeted funds for research to inform strategic and operational policy decisions related to these threats. Several problems plagued this turn as well.

1. Academics mobilized from many disciplines in natural and social sciences and humanities, but (apart from the U.S. military's war colleges and National Defense University) most had no prior familiarity with the issues, no access to classified data, and no experience with the field research needed to discipline their theories with the reality of sound data collected in conflict zones. As a result, they often relied on opportunistic and unverified data, inattentive to its limits (e.g., missing values, base rates, reliability), and interpreted through disciplinary silos (Freilich & LaFree, 2016). Financial support largely went to modeling and gaming, unmoored from the field-based time-series data needed to ground the models and give validity to their estimates. These efforts failed to adequately describe, much less anticipate, the growth and spread of transnational terrorism.

Many of these models were based on rational-choice assumptions largely unchecked against real-world data, such as the idea that young men sacrifice themselves to enhance the status and improve the life prospects of genetic kin (e.g., through payments to martyrs' families; Azzam, 2005), with noxious policy implications (e.g., collective punishment of perpetrators' families). On such accounts, even apparently irrational behaviors reflect rational calculations of the holdout's long-term interests, however incomprehensible those interests appear to us. Thus, suicide terrorists have been characterized as "holding out" for greater benefits than material interests, such as eternal glory in collective memory (again, with policy implications for collective punishment; Harrison, 2006) or a promising afterlife for one's loved ones or one's own love life, where glory or a promising afterlife is a more rewarding and hence more rational outcome than worldly greed and goods. In fact, there is little if any empirical support or testing of many of these proposals. For example, no empirical study has

ever shown that seeking virgins or a place for loved ones in paradise actually motivates martyrdom, or that collective family punishment works as a deterrent rather than stimulant to terrorism.

2. In this impoverished space, overly simple “root cause” paradigms gained currency. Some gave the central role in terrorism to socioeconomic causes (religious fervor, lack of education, poverty, marginalization, confused group identity, etc.); others invoked psychological processes (psychopathic, narcissistic, low self-esteem, suicidal, nihilistic, etc.); still others focused on political sources (opposition to foreign occupation, impediments to political expression, lack of civil liberties, etc.). These explanations became hammers seeking nails even as more complex data became available.

Thus, influential work by Alan Krueger (later chairman of the White House Council of Economic Advisors) and Jitka Malečková (2003) examined an array of available but admittedly “sketchy, incomplete and possibly nonrepresentative” data related mostly to the Palestine–Israel conflict but also Lebanese Hezbollah and hate crimes in New York. Analyses showed no effect of individuals’ income and education, leading to the hypothesis that well-off individuals “are better suited to carry out individual acts of terrorism than impoverished illiterates” because they have requisite levels of interest, expertise, and freedom from a subsistence grind to make costly commitments. Another study, focusing on an opportunity sample drawn from very different populations (people attempting to assassinate U.S. presidents, rampage shooters, suicide attackers from various parts of the world), found sampled individuals to be marginal members of society with low self-esteem, prone to suicide terrorism because they had mental problems or nothing left to lose (Lankford, 2013). In many such studies, sampling choices related both to availability of data and notions of what constitutes “terrorism” vitiate overall reliability and generalizability of results, no matter how statistically significant for the samples at hand.

3. Recognizing the need to integrate diverse data, while still limiting access to classified data, the USG developed an arm’s-length strategy, asking researchers to develop algorithms for theory-agnostic, big-data-driven exploratory work, which researchers with clearance could apply, hoping to discern patterns. Although big data can detect subtle correlations that

smaller datasets can miss, they cannot reveal which correlations are meaningful or misguided absent a theoretical frame based on real-world experience. A big-data analysis might reveal that, from 2008 to 2011, slowdown in economic activity in Western countries was well correlated with a slowdown in major terrorist activity. But the correlation itself does not tell whether there is any interesting causal relationship (likely not).

Reliance on big data alone for insight is like trying to intuit physics directly from meter readings, without theory to make sense of their relevance. Even when big-data analysis reveals important patterns, those patterns can change over time and make continued reliance on prior patterns highly problematic (Lazer, Kennedy, King, & Vespignani, 2014). When patterns involve people (rather than, say, weather), adaptation to policies is not only possible but likely, rendering prior correlations invalid. For example, it makes sense to find patterns in breakage of sewer pipes to better allocate resources for preventive repair; but allocating more police to locations based on patterns of drug sales or prior terrorist activity is likely to result in a change in those patterns. Moreover, the larger the dataset, the greater the possibility of spurious correlations.

A telling case of apparent failure of big data concerns Umar Farouk Abdulmutallab, the Nigerian man jailed for attempting to bring down Northwest flight 253 over Detroit in 2009, with a bomb hidden in his underwear. Although his own father reported Umar's radicalization and likely action to U.S. authorities, this "data point" went unnoticed in what President Obama described as an "overall systemic failure" of U.S. intelligence (White House, 2010). According to Alan Bersin, then-Assistant Secretary of International Affairs for the U.S. Department of Homeland Security (DHS): "The government's post-September 11 attempt—looking at every piece of data—was a failure"; only by "making the proverbial haystack smaller" can big data help by differentiating among risks (Konkel, 2013).

Importance and Need for Field Research, Including in the Analysis of Big Data

Without knowing what is happening in the field, academic researchers must spin their wheels. Few academic researchers interview actual terrorists or

have access to observations collected by those with security clearances. Interviewing terrorists requires considerably greater effort (preanalysis investment in time, travel, personal safety, etc.) than perusing data on paper or on an office or home computer. Granted, there are limits to the scientific value of much interview data: The setting, which is often not well-described for the limited data available, can constrain and bias responses (how the interviewer gained access to the interviewee, where the interviewee was before and after the interview); interviews may be strongly affected by interviewer and interviewee personalities; the ordering of questions may not be systematic across interviews and, if systematic, order can strongly bias responses (especially when between-subjects question design is not possible among small opportunity samples); many of those interviewed are no longer active terrorists and often are in a frame of mind and setting very different from when they were active; and so forth (Horgan, 2012). Without grounding in rich field data, theory-driven analysis can be as potentially meaningless or misleading as theory-agnostic data mining.

Approaches such as machine learning (Davulcu & Woodward, 2015) and multilingual text analysis (Grimmer & Stewart, 2013) offer possibilities for mining vast quantities of data for patterns and indicators that can elude human observers (Johnson et al., 2016). Realizing their potential will require embedding the technology in the research environment described here. Theoretical and field knowledge are needed to create culturally sensitive training data that the technology needs: to narrow the search space and find real-world relevance in the patterns revealed, and to be alert to adversaries' adaptive changes in communication and usage that can undermine the usefulness of archived observations (Hirschberg & Manning, 2015). ISIS's success can be attributed, in part, to its own fieldwork, for example, when learning the nuances of words and social connections needed to enlist followers.

An essential barrier to innovative field research, then, is inertia, which is no less punishing for being a mundane fact of life. Absent strong incentives and clear alternative directions, people and institutions do what they've always done, however great the challenge. When a strategy is failing, they tinker with it. In science, that inertia expresses itself in addressing radically new phenomena with modest extensions of existing research bound to each discipline's particular and often exclusive standards for framing theories,

methods, and controversies. Freed of these institutional and disciplinary constraints, our adversaries may understand us better than we understand them, and adapt their practices more agilely.

Academic researchers can partially address these problems by incurring the costs and risks of getting into the field or, absent that, establishing work relations with those who do. Interpretation of field data can benefit from independent readings by scientists with alternative perspectives and opportunities for developing and refining the theories that those data suggest. Such analysis is better grounded, and easier, when field research protocols are jointly designed (e.g., how their setting is staged and described, how questions are formulated and their flow structured).

Further Limits on Research: Government Funding and Institutional Review Boards

Although the need for broadly informed field research should be obvious, the USG support has been meager. DoD funding for social science has been no more than 2% of its annual \$5–6 billion budget for science and engineering research for the last few years (National Science Foundation, 2017a). Similarly sparse is federal funding for psychology and social science research at universities (\$958 million of \$16 billion, less than 6%, for basic research in 2016; National Science Foundation, 2017b), basically flat funding for the last decade, which some in Congress want to cut completely despite its critical contributions to the national interest in business, technology, medicine, and defense (National Science Foundation, 2017c).

The lion's share of DoD resources devoted to social science and “cultural knowledge” went to programs such as the Human Terrain System—Military Intelligence Program, which sought to embed experts in combat units to “provid[e] social and cultural decision-making insight to operational commanders and their staff” (DoD, 2011). By the time the Human Terrain System shut down in September 2014, the program had cost American taxpayers more than \$700 million for efforts generally shunned by the academic community and deemed ineffective or worse by many military commanders (Gezari, 2015). A 2010 Army investigation found that the program relied on unaccountable contractors, who often padded labor and

equipment expenses, and inadequate government oversight of survey efforts, evaluation of Human Terrain team interventions among the local Iraqi population, and effects on the military's cultural understanding, tactics, or strategy in the Iraq theater or elsewhere (DoD, 2010). There was also reluctance among good scientists to join the effort.

In 2008, then-U.S. Defense Secretary Robert Gates, aware that many social scientists had rejected cooperation with the military ever since the Vietnam War (1955–1975), instituted Minerva: a basic social science program “to engage additional intellectual disciplines—such as history, anthropology, sociology and evolutionary psychology” to meet challenges that “require a much broader conception and application of national power than just military prowess” (Department of Defense, 2016). Minerva represents the most sustained and consequential USG effort at basic research on global conflict, with a focus on the spread of violent extremism. Its researchers have published broadly and provided policy-relevant information in Congressional testimony and briefings to senior military. For example, the Empirical Studies of Conflict Project has developed into a growing policy-relevant research community that partners the USG with major universities (Princeton; Stanford; University of Chicago; University of California, San Diego).⁷ The Climate Change and African Political Stability project has studied conflict related to climate change, which informed the 2014 report of the Intergovernmental Panel on Climate Change. Still, Minerva is understaffed and underfunded, comprising less than 2% of the DoD's basic research budget (\$28 million of \$1.7 billion; DoD, 2016).⁸ The DoD has not allocated a single government position for management of the Minerva program, and under \$10 million annually goes to scientific research that has a field component. Moreover, although Minerva strongly encourages field-based research in highly competitive, multi-institutional and multidisciplinary projects, desk-based research can have an advantage given its faster publication rate.

A key challenge facing field research projects arises from legal and ethical protocols designed to inoculate the DoD against charges of spying and interference, and against abuse of human subjects. Although such protocols do often serve these purposes, in some contexts they make little or no sense. For example, host-country authorization is often unobtainable for a country in which government control is too weak (e.g., during civil war) or

too strong (e.g., preventing research a ruling power doesn't like). In countries with strongly independent educational and cultural institutions with which Minerva researchers seek to collaborate, or with institutions that desire to become more strongly independent, the requirement for government approval and oversight may be viewed by those institutions as a threat to their intellectual freedom, objectivity, and integrity (much as if a U.S. university were required to seek government approval of research topics and study design).

As an example of the new terrain posed by today's violent extremism, captured ISIS fighters cannot be interviewed, whatever protection is accorded them (anonymity, consent, etc.), because academic institutions require prisoners to have representatives on their Institutional Review Board (IRB). However, having any direct representative would violate a Supreme Court Ruling (*Holder v Humanitarian Law Project*), prohibiting participation of members of any organization on the USG's terrorism list in any humanitarian endeavor. Even if the USG grants approval to human subjects, each academic institution is free to make its own determination, which can vary from institution to institution and year to year, but which is usually attuned to protecting sensibilities of U.S. college students (e.g., avoiding intellectual or emotional discomfort, such as naturally occurs in distressed environments and war zones).

One possible remedy is to move responsibility for such cases to a national IRB, properly constituted with legal, ethical, and scientific expertise, including familiarity with the missions that such research can serve. That national IRB would need to be protected from political and financial pressures. Having an address for concerns might avoid situations such as the American Psychological Association's now-repudiated involvement with torture. Its jurisdiction would be something like (narrowly defined) research with a National Security Designation on Research with foreign populations.⁹

AN ILLUSTRATION OF FIELD-BASED SCIENTIFIC RESEARCH ON VIOLENT EXTREMISM

Devoted Actors versus Rational Actors

Our research team (ARTIS International; *artisinternational.org*) of academics, policymakers, former military, and experts on cultural issues (playwrights, journalists, actors, etc.) has been exploring why people refuse political compromise, go to war, and attempt revolution or resort to terrorism, focusing on what Darwin called virtues “highly esteemed and even sacred” that give “immense advantage” to any group inspired by devoted individuals willing to sacrifice for them (Darwin, 1871, pp. 159–160; see, in this volume, A. Cohen & Neuberg, [Chapter 32](#), and Miller, Wice, & Goyal, [Chapter 16](#)). The theoretical frame emerges from our prior online, laboratory, and field studies of conflict situations, most recently among combatants on the ISIS frontline in Iraq (Atran, 2016a; Gómez et al., 2017). The studies suggest that seemingly unconditional cooperation and intractable conflict are best understood within a devoted actor rather than rational actor framework that integrates research on “sacred values”—whether religious or secular—and identity fusion, which gives a visceral sense of group oneness and invincibility (Rappaport, 1971; Baron & Spranca, 1997; Graham & Haidt, 2012; Swann, Gómez, Huici, Morales, & Hixon, 2010; Buhrmester, Fraser, Lanman, Whitehouse, & Swann, 2014).

In September 2014, U.S. President Barack Obama endorsed the declaration of his national intelligence director: “We underestimated ISIL and overestimated the fighting capability of the Iraqi army. . . . It boils down to predicting the will to fight, which is an imponderable” (Payne, 2014). This shortfall may arise, in part, from undervaluing certain aspects of what may be considered the nonutilitarian dimension of human conflict, which combatants themselves deem “sacred” or “spiritual,” whether secular or religious. Over the last 2 years, members of our research group at ARTIS International and the Centre for the Resolution of Intractable Conflict (CRIC) at the University of Oxford have been working in Western Europe, North Africa, and the Middle East to understand people’s willingness to make costly sacrifices for their groups and their values, including the will to fight and to die.

To examine this dimension of intergroup conflict, we developed measures based on ethnographic fieldwork and interviews with two groups on the USG list of terrorist organizations in northern Iraq in February–March 2015: captured fighters of the Islamic State (ISIS, ISIL), and combatants of the Kurdistan Worker’s Party (PKK) fighting against the

Islamic State. Next, we tested and refined these measures with large-sample online studies in Spain to understand people's willingness to make costly sacrifices for their groups and their values.

The preoccupation with understanding those who seek to join ISIS has led us to largely overlook a related phenomenon. Just as foreigners from around the globe have flocked to ISIS's so-called "Caliphate," so too have others, and for different reasons, rallied to *fight* ISIS. Accordingly, we followed with a quantitative field study in February–March 2016 on the same frontline with Peshmerga (Kurdish Regional Government forces), Iraqi army Kurds, and Arab Sunni militia. Further online studies in Spain with Western Europeans then examined cognitive mechanisms underlying frontline results in the Middle East.

From our studies, three interrelated factors appear to be critical to willingness to kill and sacrifice: (1) commitment to non-negotiable sacred values to which the group's actors are wholly fused; (2) readiness to forsake commitment to kin for those values; and (3) perceived spiritual strength of one's own group versus foes. The following paragraphs briefly describe the experimental measures and results for each factor.

To measure sacredness, we probed willingness to trade-off values in exchange for material benefits, whether for individual or collective gain. Much more is known about economic decision making than about value-driven behavior. But here are some features of sacred values that we, and others, have empirically identified:

1. Disregard for material incentives or disincentives: Attempts to buy people off ("carrots") their cause or punish them for embracing it through sanctions ("sticks") don't work, and even tend to backfire (Atran, Axelrod, & Davis, 2007; Dehghani et al., 2010).

2. Blindness to exit strategies: People cannot even conceive of the possibility of abandoning their sacred values or relaxing their commitment to the cause; this fosters unconditional cooperation and intractable conflict in ways that social contracts born of shared convenience and utility do not. Offering material incentives, however reasonable or rewarding, or sanctions and punishments to abandon or compromise sacred values increases anger, violence, and opposition to peace.

3. Resistance to social pressure: It matters not how many people oppose your sacred values, or how close to you they are in other matters; sacred values are not social or cultural norms but defining and circumscribing features of culture itself (Sheikh, Ginges, & Atran, 2013).

4. Insensitivity to discounting: According to most economic and political theory, and in most everyday affairs, distant events and objects have less significance for people than things in the here and now; but matters associated with sacred values, regardless of how far removed in time or space, are more important and motivating than mundane concerns, however immediate (Ginges, Atran, Sachdeva, & Medin, 2011).

5. Privileged link to emotions: for example, anger and rage when sacred values are threatened; joy and happiness when successfully defending sacred values, including by way of revenge (de Quervain et al., 2004).

6. Distinct neural signatures: For example, our brain scans of supporters of al-Qaeda affiliate Lashkar-e-Taiba on willingness to fight and die for sacred values show diminished activity in areas associated with utilitarian reasoning, indicating inhibition of deliberative reasoning in favor of rapid, duty-bound decision making (Berns et al., 2012).

Absolute refusal to contemplate such trade-offs was taken as an indicator of a sacred value. For identity fusion, participants were asked to indicate their relationship to a number of groups. They were shown a series of increasingly overlapping circles, one of which represents them, and the other, a given group (Swann et al., 2009). Respondents who picked the figure displaying completely overlapping circles were considered fused with the group, leading to a dichotomous measure. For example, those who chose the last pairing in [Figure 31.1](#), “E,” expressed actions markedly different from those who chose other pairings, indicating that their personal identity is bound to a unique collective identity, with each individual ready to sacrifice for every other.

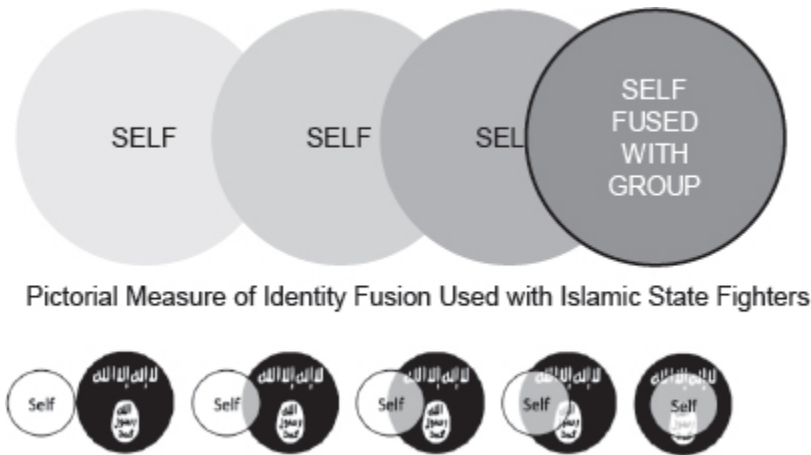

FIGURE 31.1. Measures of identity fusion. Top: generalized dynamic slider version for tablet or smartphone. Bottom: static pictorial version used with Islamic State Fighters on plastic card. People who choose the fused option (placing the “me” circle entirely within the group circle) think and behave differently than people who choose any other option.

Our previous online and field studies in North Africa and Western Europe indicated that commitment to sacred values and identity fusion independently affect willingness to make costly sacrifices, but that their interaction maximizes such willingness under real or perceived threat (Figure 31.2). For example, among 260 Moroccans who lived in either of two city neighborhoods with a history of support for militant *jihad* (Jemaa Mezuak in Tetuan and Sidi Moumen in Casablanca), individual testing in the field indicated that about 30% were “devoted actors” (i.e., driven by duty-bound, deontological, considerations rather than rational anticipation of costs and consequences, risks or rewards). In the Moroccan case, these were people who viewed strict imposition of Islamic law, or Sharia, as a sacred value, and who identified closely with a kin-like group with which they were “fused.” They were also the most willing to kill and die for Islamic law. A parallel study of 644 people in Spain identified only 12% as devoted actors willing to sacrifice for democracy, and few willing to kill, die, or forsake family, even when reminded of threats by ISIS and al-Qaeda. Those most likely to make costly sacrifices saw democracy as a sacred value and also identified closely with a kin-like group of friends (Sheikh, Gómez, & Atran, 2016).

FIGURE 31.2. The devoted actor: interaction of sacred values and identity fusion. In ISIS-supporting Moroccan neighborhoods, people who viewed strict imposition of Islamic law, or Sharia, as a sacred value and who identified closely with a kin-like group (“fused”), most expressed willingness to kill and die for Islamic law (left graph). A sample of Spaniards reported a weaker willingness to kill and die for democracy as a sacred value when identifying closely with a kin-like group of friends, and only under an explicit threat priming (right graph). From Sheikh, Gómez, and Atran (2016).

For Cause and Comrade: “Will to Fight” on the ISIS Frontline and Elsewhere

In February–March 2016 we interviewed combatants near the village of Kudilah, the first engagement in the offensive to retake Mosul, the largest

ISIS-controlled city (Atran, 2016a). At Kudilah, some 90 ISIS fighters with no heavy weaponry managed to prevent a sustained advance by several hundred coalition forces of Arab Sunni militia, Iraqi army, and Kurdish Peshmerga, aided by U.S. and German advisers and repeated air strikes. This occurred, despite the fact that more than 50 ISIS fighters were killed in the battle, including a score of *inghamasi* (“those who plunge deep,” suicide attackers trained for piercing enemy positions and for covering retreat), yelling that they would die so that “The Caliphate is enduring and expanding!” Many who fought in the battle, including some who had been fighting in various wars since the 1960s, told us this was the fiercest combat of their lives.

We wondered whether there were common traits that explain the fierce devotion of ISIS fighters, as well as fighters opposing ISIS. As we noted, researchers usually treat extreme sacrifice for others in utilitarian terms, weighing pros and cons in ways that best satisfy their own interests even if others benefit as well. But it is difficult to see how that applies to *inghamasi* or to Kurdish fighters who have already lost limbs and left their families behind in ISIS territory to defend “Kurdeity” (their term). Calling one side “losers/nihilists/insane/barbarians/cowards,” as our press and politicians frequently do, versus labeling the other side “heroes/altruists/courageous/civilized/brave” may be relevant for mobilizing sentiment, but it has little apparent scientific worth for distinguishing sides.

We examined will to fight among the three anti-ISIS groups that fought at Kudilah. Both the Peshmerga and Iraqi regulars were Kurds, and all groups identified as Sunni Muslims. We intended to interview 20 combatants from each group, but difficulties in getting to the front, the wounding or death of planned interviewees, and changes in military scheduling prevented achieving total parity between the groups before the second battle of Kudilah began in late March 2016. Values considered sacred for Peshmerga and Iraqi Army Kurds were mainly “Kurdeity” (a cultural concept denoting a sense of Kurdish language, heritage and land, 63 and 41%, respectively) and Independent Kurdistan (a political goal, 26 and 47%, respectively). For Sunni Arab fighters, maintaining the integrity of the Iraqi nation (a political goal, 55%) and Arabness (a cultural concept, 20%) was considered sacred. The different groups with which Peshmerga, Iraqi Army Kurds, and Arab Sunni militia participants might be fused were family (95,

94, 100%, respectively), kin-like group of friends (95, 82, 94%, respectively), Muslim Ummah (26, 19, 39%, respectively), Iraqi People (0, 12, 61%, respectively), and own group (79, 100, 56%, respectively).

All anti-ISIS combatants were fused with at least one group whose members were perceived as sharing at least one sacred value. All were constantly under threat and were putting their lives on the line, as is evident from the fact that more than half of frontline participants had been wounded in battle (Table 31.1). Those wounded expressed greater willingness to make costly sacrifices, indicating convergence between stated and actual willingness to make costly sacrifices on the front.

TABLE 31.1. Peshmerga Are More Likely to Express Willingness to Make Costly Sacrifices Than Iraqi Army Kurds or Sunni Arab Militiamen

Group	<i>n</i>	Wounded	Sacrifices <i>M</i> (<i>SD</i>)
Peshmerga	19	12 (63%)	2.56 (1.07)
Iraqi Army Kurds	17	8 (47%)	1.82 (0.95)
Sunni Arab Militia	20	9 (45%)	1.70 (1.13)

We tested our measures of sacred values and fusion online ($N = 816$). Participants responded to measures of fusion with country (Spain) and democracy as a sacred value. Under an explicit threat condition highlighting the 2004 Madrid train bombings, an interaction of identity fusion and sacred values characteristic of “devoted actors” appeared: Devoted actors in the threat condition displayed the strongest willingness to make costly sacrifices.¹⁰

Previous studies of combat soldiers stress devotion to comrades over cause (Stouffer, Suchman, De Vinney, Star, & Williams, 1949; Smith, 1983; Moskos, 1975; Whitehouse, McQuinn, Buhrmester, & Swann, 2014) as do online studies of Western Europeans (Gómez, López-Rodríguez, Vásquez, Paredes, & Martínez, 2016). However, this may be otherwise when combatants consider the cause sacred. In in-depth interviews with (captured) ISIS and PKK (Kurdish Marxist) combatants in Iraq in 2015, some told of how they had to give up their families to fight for their cause (Islamic Caliphate, Kurdish homeland)¹¹; and in fact, ISIS has divulged

children's public executions of parents for opposing the Caliphate and its leader (Taylor & Moyer, 2016; Ahlul Bayt New Agency, 2016).

From a material and evolutionary perspective, one should prioritize kin or kin-like groups over abstract ideals. Yet one finding of our qualitative frontline interviews is that combatants make painful decisions when prioritizing value over group. We empirically tested how people reason over such trade-offs, and to what extent they predicted willingness to fight, in a sequence of studies. We asked participants to choose between sacred values and fused groups. All combatants were devoted actors who regarded relevant values as sacred and were fused with at least one larger group: comrades, Muslim Ummah, kin-like group of friends (often comrades in arms), Iraqi people, or their own groups (Peshmerga, Iraqi Army Kurds, Sunni Arab militia). Most were also fused with their families ($\geq 90\%$ for all three groups). We pitted their two most important groups against their two most important sacred values whenever possible. Most combatants chose at least one value over a group (86%), with more than half of them choosing at least one value over their families (59%). Combatants scored more highly in the costly sacrifice scale if they chose the value over the group in general (Figure 31.3).

FIGURE 31.3. Willingness to make costly sacrifices for participants who forsake their fused groups for sacred values in frontline and online studies. From Gómez et al. (2017).

On a more general plane, these findings of apparent preference for value over kin by devoted actors provide empirical support for the thesis that humans may form their strongest (and potentially most expansive) political and religious ties by subordinating devotion to kin to a more abstract ideal. Indeed, a founding parable of monotheistic religions involves Abraham’s willingness to sacrifice beloved progeny to signal devotion to a sacred value (absolute commitment to God). The very term *Islam*, or “submission,” refers to subordinating tribal and all other prior group affinities to God’s message. Historically, willingness to sacrifice family and tribe was arguably critical to construction of larger groups founded on political principles (Fukuyama, 2012).

Within a rational actor framework, perceived intergroup difference in material formidability would strongly relate to willingness to engage in costly sacrifices. In contrast, within a devoted actor framework, perceived spiritual formidability would be most relevant when sacred values are in play. Although the term “spiritual formidability” may have religious connotations to some, it more properly refers to nonmaterial strength. In the frontline and online studies, we find that relative spiritual formidability of

groups, compared to relative physical formidability, is more related to willingness to sacrifice.

Using techniques to judge physical formidability (Holbrook & Fessler, 2013) that assessed the perceived strength of various combatant groups in Iraq, we found that both avowedly religious ISIS fighters and avowedly secular PKK fighters (the only force that held fast against the ISIS onslaught in summer 2014) disregarded consideration of ingroup and outgroup physical formidability. They argued during our initial experiments in early 2015 that most important was spiritual formidability (*ruhi bi ghiyrat*, in both Arabic and Kurdish, or “spirituality with bravery” to defend what is most cherished, which they recurrently described in terms of “strength of belief in what we are fighting for” and “what is in our heart”). Thus, we adapted dynamic measures of physical formidability to spiritual formidability to compare the effect of the ingroups’ perceptions of their own physical versus spiritual formidability on willingness to fight, as well as the ingroups’ perceptions of the physical versus spiritual formidability on the willingness to fight of various outgroups, whether friend or foe.

Frontline combatants’ perception of spiritual formidability positively correlated with willingness to make costly sacrifices. These costly sacrifices to defend the value were dying, letting their family suffer, killing civilians, undertaking a suicide attack, and torturing women and children. Combatants also judged the United States to be high in physical formidability but low spiritually, while judging ISIS low physically but high spiritually (Figure 31.4). A fighter typically remarked: “They are weak now because they have used up their resources but their fighters don’t retreat even if the battle is lost.”¹²

FIGURE 31.4. Comparing combatant forces in Iraq: physical versus spiritual formidability. In testing in Iraq, a captured ISIS fighter, left, chose how to mask himself to ensure anonymity to conform with human subjects safety protection. ISIS fighters (here using a static paper measure with discrete choice) and Kurdish fighters (using either a static measure or a dynamic measure on the iPad allowing continuous choice) depict U.S. military physical force as strong and its spiritual force as middling. The same men portray Islamic State physical force as weak and spiritual force as strong.

Follow-up online studies in Spain ($N = 1,434$) further explored possible effects of spiritual and physical formidability on willingness for costly sacrifices and armed intervention. Participants responded to a five-item scale about their willingness to engage in actions to defend the value using a Likert scale: *lose my job or source of income/go to jail/use violence/let my children suffer physical punishment/die*. (Quest for variance in responses motivated use of different sets of costly sacrifices for frontline combatants and European noncombatants.) Participants who perceived the Islamic State as spiritually strong were least willing to sacrifice for democracy and support the country in an armed intervention.¹³ When participants were asked to estimate the spiritual formidability of Spain versus the Islamic State, they invoked negative emotions (fear, panic, defenselessness, anger) when perceiving the Islamic State as spiritually stronger than the ingroup. Together, the Spanish findings suggest that perception of an adversary's great spiritual strength relative to one's own may hamper and deter willingness to sacrifice in opposing the adversary. In summary, we consistently find that the relative spiritual but not physical formidability of groups predicts willingness to engage in costly sacrifices. This was true for combatants and online noncombatants.

Although these studies do not directly focus on transnational terrorism, they were motivated by earlier and parallel ethnographic fieldwork, semistructured interviews, and pilot experiments with ISIS and PKK (both groups being on the official USG list of terrorist organizations). This research with ISIS and PKK proved highly relevant to how those fighting ISIS perceive and act upon ISIS's will to fight relative to their own. The unsolicited responses (controlling and monitoring for possibilities of deception) of captured ISIS fighters, and PKK fighters holding the line against ISIS, regarding what is sacred and spiritual were spontaneously echoed by other frontline combatants.

The numbers of ISIS and PKK fighters interviewed were too few for statistical analyses; however, insights gained with them were directly responsible for the elaboration of measures that we validated in a number of studies among a wider group of combatants and a much larger group of noncombatants from an entirely different cultural context. The fact that these hypotheses-driven measures reliably elicited statistically significant responses in the direction intimated by the ISIS and PKK interviews suggests that the information from ISIS and PKK fighters was both genuine and generalizable. More broadly, our findings suggest that insights gained from studies on the ISIS frontline are theoretically and methodologically robust among large samples of noncombatants in an entirely different cultural context.

Understanding the will to fight in the face of lethal danger may remain imponderable—and attendant security challenges seemingly intractable—as long as we view such actions through a narrow lens of instrumental rationality (Toynbee, 1934). This optic tends to disregard the immediate and remote consequences of actions motivated by highly esteemed, even sacred spiritual and moral virtues that, as Darwin noted, “will certainly give an immense advantage” to one group over another when possessed by devoted actors who would “by their example excite . . . in a high degree the spirit” in others to sacrifice self for cause and comrades—whether for ill or good (Buckley, 2017).

The Importance of Social Networks: Counterengagement versus Counternarratives

There is a pervasive belief in governments and nongovernmental organizations (NGOs) that—short of physical elimination—offering jobs or education or spouses to volunteers for value-driven militant groups would be the best way to reduce violence and counter the *jihadi* pull. But long-term analyses by the World Bank indicates no reliable relationship between job production and violence reduction. If people are ready to sacrifice their lives or their family—the totality of their self-interests—then it is not likely that offers of greater material advantages will stop them. Although such incentives may provide viable alternative life pathways at initial stages of radicalization, research shows that fully radicalized individuals who are fused with their group and its values are not particularly susceptible to such material incentives or disincentives (punishments, sanctions), which often backfire by increasing support for violence.

Research also shows that most who originally joined al-Qaeda were married (Sageman, 2004), and prior marriage does not seem to be a deterrent to those now volunteering for ISIS. Among the senior ranks of such groups, there are many who have had access to considerable education—especially in scientific fields such as engineering (Gambetta & Hertog, 2016) and medicine (Bergen & Lind, 2007) that require great discipline and a willingness to delay gratification. Indeed, ever since the anarchist movement beginning in the late 19th century, this sort of specialized preparation holds for much of the leadership of insurgent and revolutionary groups.

Commitment to absolute values that cannot be refuted by logical argumentation or empirical counterevidence—as with core religious precepts and axiomatic secular ideologies—may be paramount in sustaining extreme behaviors for the betterment or harming of others (Atran & Ginges, 2012). But such values can only generate successful actions by being embedded in social networks, inspiring and mobilizing groups of people bound by those values as “imagined kinship” (think brotherhood or motherland) and ready to sacrifice for one another unto their last measure of devotion.

A very senior member of President Obama's administration told our research team that when the operations to eliminate Bin Laden were successfully concluded:

I told Congress that this won't be the end of the problem, that we have to find a message to pull people away from this movement, and we need research and funding to do this because we don't know what will work and what won't. But Congress said: "How do you quantify this. Can you produce quantifiable results for the budget?" And of course we couldn't, because this is a long-term thing whose means and results we really can't predict in advance. So we've had a very dispersed and inadequate effort by the U.S. Government to understand causes and come up with some effective messaging. . . . To deal with this we can't just let a thousand flowers bloom. We need a coordinated, global effort to meet the security challenge in the realm of ideas.

The fitful and often feckless USG counterterrorism focus in the realm of ideas is on "counternarratives," intended as alternatives to the "ideologies" held to motivate terrorists. This strategy treats ideas as disembodied from the human conditions in which they are embedded and given life, thereby animating social groups. In their stead, research and policy might better focus on personalized "counterengagement," addressing and harnessing the fellowship, passion, and purpose of particular people within their specific social contexts, as ISIS often does. This focus stands in sharp contrast to current reliance on negative mass messaging and on sting operations to dissuade young people in doubt through entrapment and punishment (the most common practice used in U.S. law enforcement)¹⁴ rather than through positive persuasion and channeling into productive lifepaths.

Reports from the The Soufan Group, International Center for the Study of Radicalisation (King's College) and the Combating Terrorism Center (West Point) indicate that approximately three-fourths of those who join the Islamic State at home or abroad do so in groups. These groups often involve preexisting social networks, and typically cluster in particular towns and neighborhoods (Perliger & Milton, 2016). This clustering suggests that much recruitment does not owe primarily to direct personal appeals by organization agents or individual exposure to social media (which would entail a more dispersed recruitment pattern). Rather, recruiting often critically involves enlisting clusters of family, friends, and fellow travelers from specific locales (e.g., neighborhoods, universities, prisons), indicating a public health rather than strictly criminal approach to violent extremism as most appropriate.

Consider, for example, the evolution of Paris–Brussels attack networks (2015–2016; see [Figure 31.5](#)) in terms of their increasing operational effectiveness via increasing reliance on local facilitation networks involving preexisting social ties (Atran & Hamid, 2015). In 2014, at least 21 ISIS operatives were sent back from Syria into Europe to carry out attacks on soft targets. All were Francophone; most were French and Belgian, while others were citizens of former French colonies. They reentered individually or in pairs. All attacks, except one, were foiled. All were directed by ISIS’s external operations branch, EMNI (a.k.a. *Amn al-Kharji*). The attackers’ lack of local facilitation networks partially contributed to their failings. In contrast, the “success” of the November 2015 Paris and March 2016 Brussels attacks can be partially attributed to an extensive inter-European facilitation network of overlapping, and largely preexisting, local social ties—including many individuals with no direct involvement in, or even knowledge of, the planning or execution of violent actions. Twelve individuals implicated in both attacks came from disparate French and Belgian recruitment networks—each of which had its own local facilitation networks—including the two heads of EMNI’s European branch that “masterminded” the attacks.

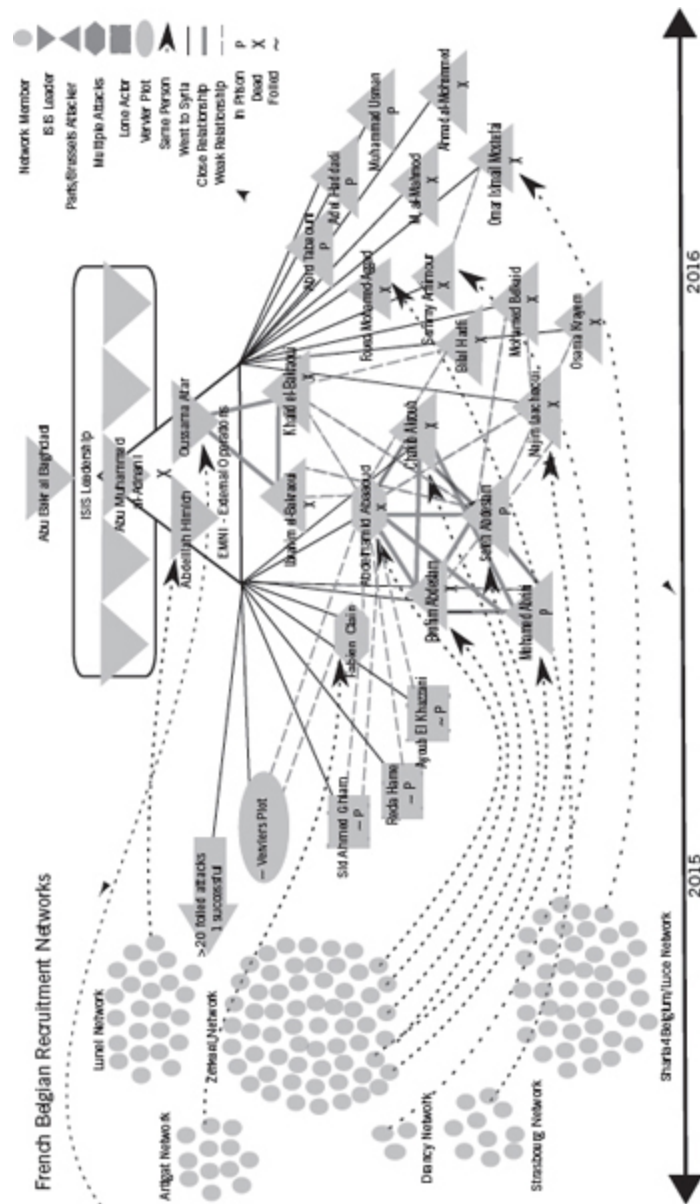

FIGURE 31.5. Evolution of Paris–Brussels Attack Networks (2015–2016). Initially, authorities did not figure out the link between these attacks, until they identified a common middleman, Abdelhamid Abaaoud. Abaaoud was again implicated as a middleman in a series of foiled EMNI-directed group and lone-actor attacks in France in early-to-middle 2015. By this time, Abaaoud became known as “the most wanted terrorist in Europe.” As a result, his ability to be an effective logistical middleman was diminished (ISIS faked his death to help his operations), and he needed to outsource his role to others. Five of Abaaoud’s childhood friends from Molenbeek, and fellow Zerkani network recruits, began exploiting family, friends, and underworld connections in Belgium and France to set the stage for the attacks. Only one of these trusted allies had never been to Syria: Salah Abdeslam. Salah’s low or nonexistent profile in European terrorism databases allowed him to take over the crucial middleman role. He arranged housing, transportation, picked up attack network members returning from Syria, and so forth. Many members of the attack network contributed facilitation sources, but the Molenbeek friends with the closest social ties were the primary coordinators of these resources. In the

months following the attacks, over 200 individuals were arrested in over 20 countries on charges of facilitation. In 2016, at least 20 more attack plans in France were either inspired or directed by ISIS, 17 of which were foiled. In most cases, attackers were recruited, coordinated, and instructed online, with limited offline facilitation in preexisting social networks, which may account for their limited effectiveness. Source: Graph and background by N. Hamid, *Artis International*.

To counter the power of personal networks, at the very least we need field research in actual communities, capable of capturing the evidence to reveal which strategies are working, failing, or backfiring. A necessary focus of that research effort must be youth, who form the bulk of today's terrorist recruits and tomorrow's most vulnerable populations. Volunteers for al-Qaeda, the Islamic State, and many extreme nationalist groups are often youth in transitional stages in their lives—immigrants, students, people between jobs, and before finding their mates (Atran, 2010a). Having left their homes, they seek new families of friends and fellow travelers to find purpose and significance. Ability to understand the realities facing young people will determine whether the scourge of transnational terrorism continues, abates, or surges. Presently, though, young people, especially young men (although increasingly young women), are viewed mostly as a “youth bulge” and a problem to be pummeled rather than as a “youth boom” and the world's most creative force, which holds the promise of a solution to violent extremism. We need prevention research, fostering positive youth development through concrete possibilities for realizing young people's hopes and dreams—research that goes beyond seeing youth only as perpetrators, beneficiaries, or victims of others' initiatives, but as potentially having political agency (as ISIS allows), with decision-making roles in shaping their own futures.

One such success story is the *Aware Girls* program founded by teenagers Gulalai and Saba Ismail a decade ago in Northwest Pakistan. It provides young women with a platform for learning and advocacy, which has helped hundreds of young men move away from political and religious violence (Briggs, 2015). The women have trained on issues of political leadership and participatory democracy, humanitarian assistance, and the effects of terrorism on women and society more generally. They have systematically monitored general elections to ensure respect of voting rights for women and minorities, established a helpline for gender-based violence, provided HIV/AIDS prevention education for girls and young women, and

established the “Youth Peace Network” across Pakistan’s Khyber Pakhtunkhwa Province in Baluchistan, in Pakistan’s Federally Administered Tribal Areas, and in adjacent areas of Afghanistan. In turn, since 2009, they have transformed over 1,500 youth from different parts of the region, by providing in-depth training workshops and social media campaigns on human rights, peace building, conflict resolution, nonviolence, democracy, political engagement, and pluralism. In a snowballing effort, these more than 1,500 youth have reached out to at least 10,000 young men and women in their communities. Approximately 4,000 youth who have also been engaged at different levels of intensity in seminars, dialogues, and surveys, have joined the larger group working on peace.

An essential feature of such programs is that they are local, allowing personal engagement by individuals attuned to culture and conditions. There are important success stories of youth turning other youth from violence, as with the examples from Pakistan and Yemen, and, potentially, from Kosovo. But these are still local success stories. How do we proceed from local to global achievement: to sharing, generalizing and implementing successful practices, including finding common religious grounds for shared commitment and sacrifice toward peace rather war and violence?

Moving from local successes to global achievement requires institutions and programs that help weave together general principles and practices that underlie local successes, while also encouraging local initiative, tailoring, and autonomy. The United Network of Young (UNOY) Peacebuilders is one youth-led organization that follows this strategy, using baseline studies and ex-postevaluations, making the most with very limited means (UNOY Peacebuilders, 2015). It was instrumental in promoting UN Security Council Resolution 2250, which urges member states to give youth a greater voice in decision making at the local, regional, and international levels in order to better confront the threat to stability and development posed by violent extremism. The resolution’s implementation requires independent scientific research not merely on youth, but in the field with youth, to inform policies of member nations and, perhaps more important, to create transnational social and intellectual channels to allow youth to formulate and choose best practices (by also overcoming institutional inertia within the UN’s top-down, government-centered framework).

Providing the scientific foundations for that youth work, as well as interdiction and other programs for stopping violent extremism, requires fieldwork deeply integrated with basic science. It also requires integration with government to address decision makers' perceived needs, while informing them about the content, strengths, and limits to the science. To fulfill these roles, scientists must retain strong independence to avoid co-optation by bureaucratic or political interests, while maintaining their colleagues' respect. Unless the sciences are integrated and independent, government may get oversimplified views from scientists unaware of their subdiscipline's limits, or pandering ones from scientists eager for attention and influence. Unless government maintains proper distance, it will deter scientists who fear wasting time or compromising their integrity.

THE WORLD-HISTORICAL CONTEXT OF TRANSNATIONAL TERRORISM

The Age of Rage: A Fragmenting World Order

The Western creations of the nation-state and relatively open markets that today dominate the global political and economic order (and to which non-Western powers such as China and Russia now also subscribe) have largely supplanted age-old forms of governance, social formations, and economic activity. The accompanying rising populations and urbanization, extensive and rapid communications and transportation, and science and technology have transformed people in the farthest reaches of the planet into competitive players seeking progress and personal satisfaction through material expansion and success. But the increasingly unavoidable tension in the quest for material comfort and security, via participation in market-driven competition that constantly agitates for innovation and change, often comes at steep personal and social cost. This is especially so for communities and regions with little time to adapt and where aspirations show scant promise of fulfillment. As the spiritual values of long-standing cultures and religions have been eclipsed under newer institutions that lack stability or are corrupted, redemptive violence is prone to erupt from the

resulting anxiety and alienation along prevailing political fault lines (Mishra, 2017).

This was apparent in the actions of social revolutionaries and anarchists in the first wave of modern transnational terror that began shortly before the assassination of Russia's Czar Alexander II (1881). This terrorist wave extended through the assassinations of the Prime Ministers of France (1894) and Spain (1897), the Empress of Austria (1898) and the King of Italy (1900), and the killing of U.S. President William McKinley (1901). It involved bombings of "Bourgeois" civilians in cafes and theaters across Europe and North America, before abating with the onset of World War I. Affected nations reacted by adding or reinforcing state security organizations such as Russia's Okhrana, 1881, precursor of the People's Commissariat for Internal Affairs (NKVD) and the Committee for State Security (KGB); Britain's New Scotland Yard, 1890; France's Brigade de Renseignements généraux, 1907; and the U.S. Bureau of Investigation, 1908, precursor of the Federal Bureau of Investigation (FBI). Initially, however, states lashed out in stunned bafflement, often missing their elusive targets but hitting those unrelated to terrorist acts, and also using the cover of the fight against terror to mask the settling of scores against more traditional enemies.

Thus, in his first Annual Message to Congress after McKinley's death, Theodore Roosevelt declared: "When compared with the suppression of anarchy, every other question sinks into insignificance" (Roosevelt, 1901). He then offered a Corollary to the Monroe Doctrine: anarchy's "general loosening of the ties of civilized society, may in America as elsewhere, ultimately require intervention by some civilized nation, and may lead the United States, however reluctantly . . . to the exercise of an international police power" (Roosevelt, 1904). Most tellingly, the war against anarchy and terror helped to justify the brutal repression of a native insurgency against America's "civilizing mission" and rule in Muslim areas of the Philippines.

The countercultural pressures toward salvational violence against the international order are arguably similar for many who now join or support al-Qaeda and ISIS. And quite similar, too, has been the character of the international reaction to these vanguards of the recent post-Cold War wave of transnational political violence.

There are, in fact, striking political, social, and economic parallels—and arguably continuities—between the pre-World War I unraveling of the European order and present challenges to the global order established after World War II. Before the Napoleonic wars, the nation-state system was quasi-anarchic, with each nation playing close to a zero-sum game with all competitors and neighbors. The massive bloodletting and overthrow of established regimes instigated by the French Revolution and Napoleonic wars (1789–1815) compelled Europe’s governing elites to develop a quasi-institutional consensus for how Europe, and the expanding colonial world it dominated, should be managed to avoid chaos. In the century from the Congress of Vienna (1815) to the outbreak of World War I (1914), this informal international consensus persevered to maintain the integrity of existing empires and nation states—and this arrangement persisted despite important multinational popular uprisings (e.g., Revolutions of 1830 and 1848), the mass-casualty multilateral Crimean War (1843–1846), and bilateral wars (e.g., Austro-Prussian War, 1866; Franco-Prussian War, 1870–1871), which intermittently reconfigured the balance of power within and between polities. Britain, especially, recurrently intervened abroad to maintain the Ottoman Empire’s integrity and the overall European balance of great powers. But the increasingly obvious gap separating elite values and actions from popular needs and wants, and the willingness of one, then the other, of Europe’s powers to break the consensus (e.g., as with Russia around its borders and in the Balkans and then, in 1911, with Italy seizing parts of Ottoman North Africa to make Libya) speedily unwound the world order.

This order had attained spiraling levels of globalization in transportation (worldwide construction of roads and railroads, steam shipping of waterways, and later automobiles), communication (e.g., telegraph, and later telephone, film and radio), unfettered capital flow (not recovered to 1912 levels until the 1990s), movements of people (only Russia and Turkey required passports), and scientific prowess and reach (with new sources of technology and energy freeing human material effort and creation from muscle power). Yet when nations again focused narrowly on self-interests (as with other great powers like Germany, which felt unduly left out of the colonial quest for empire), and the failed crusades for international brotherhood devolved into anarchism to become a transnational scourge, the world order rapidly degenerated into world war, with disregard for

accepted red lines of national sovereignty and balance of power only accelerating in the lead up to World War II. In *The Escape from Freedom*, Eric Fromm (1941) argued that the anxiety that results from what religious philosopher Kierkegaard called “the dizziness of freedom” (Kierkegaard, 1844/2014) and the resultant social disruption impelled many people to seek the elimination of uncertainty in authoritarian systems, as with Nazism and Stalinism in the period between the two world wars.

The quest for elimination of uncertainty, coupled with what social psychologist Arie Kruglanski and colleagues (2014) deem “the search for significance” are the personal sentiments most readily elicited in my research team’s studies of both volunteers for violent *jihad* and militant supporters of populist ethnonationalist movements. The yearning for significance and certainty, in turn, lead to what cultural psychologist Michele Gelfand and colleagues describe as a “tightening” of political cultures toward more authoritarian leadership, diminished tolerance, and greater punishment for deviant and even different behaviors from the desired norm (Gelfand et al., 2011).

Today, the speed, scale, and scope of change in a globalization movement is again unsettling Western societies. Yet the spiraling impact of globalization now extends to the rest of the world whose populations have much less prior experience than the West in adapting to the political, social, and economic effects of market-driven “creative destruction.” In the West, traditionally left-leaning working-class communities that have been disadvantaged by economic globalization, and traditionally right-leaning believers in cultural ideals that they feel are threatened by multicultural globalism, have joined populist movements that reaffirm the primacy of the nation-state, reject international alliances, abhor political correctness and the push for cultural diversity, and distrust traditional governing elites. In other parts of the world, there has been a multiplication of failed states, insurgency and war, and massive population displacements. This, in turn, has fostered the implantation of transnational terrorist movements in these regions. From their bases in failed states, these movements are then able to reach out and into increasingly marginalized immigrant communities in Europe and elsewhere in order to destabilize those host societies. The terrorists’ actions end up increasing the host society’s hostility against

immigrants and other marginalized groups, and this hostility encourages people from those groups to enlist into the terrorists' cause.

The situation is not irredeemable, but it is approaching a dangerous threshold. Mainstream middle classes (the mainstay of democracies everywhere) are experiencing a collective loss of community and increasing alienation from governmental elites and are joining the underemployed working class in blaming marginalized immigrant groups for societal ills. Meanwhile, radical Islamists earnestly, and with increasing success, drive the majority-culture mainstream from Muslims, with brutal acts intended to heighten sentiments of blame among the mainstream and victimhood among immigrant Muslims. The aim is to make these immigrants realize that trying to live in peace brings only pain. This situation is occurring against a backdrop of general demographic decline (a replacement rate of only 1.6 children per couple in the EU). This demographic problem increasingly hampers European countries from sustaining a large middle class, much less armies, without massive immigration to which the European mainstream is increasingly opposed.

The Vitality of Values

The values of liberal and open democracy increasingly appear to be losing ground around the world to those of radical Islam and narrow xenophobic ethnonationalisms. They are in a tacit alliance that is clobbering societies in ways similar to the hatchet job on republican values by the fascists and communists in the 1920s and 1930s. According to the World Values Survey (Waves 5 and 6, 2005–2014), only 40% of Europeans under age 30 years believe that living in a democratic country is “absolutely important” to them (World Values Survey, 2005–2014). In Germany, support for democracy is weakest in former East Germany. There, more than one-fourth of men supported the anti-EU and anti-immigrant party, Alternative for Germany, in the September 2017 general elections. As a result, the far-right has an official presence in Germany's national parliament (*Bundestag*) for the first time in more than half a century (Oltermann, 2017). In Hungary, a revanchist expansive nationalism is advocated by the ruling national conservatives (*Fidesz*) and far-right Jobbik party (claiming rights to

“protect” large communities of ethnic Hungarians in nearby countries). Prime Minister Orbán, who was expelled from Liberal International, a global coalition of centrist liberal democrats, is now Europe’s leading apostle of what he calls “the illiberal state,” citing Russia and China as examples (Mahony, 2014). (Jarosław Kaczyński, head of the populist Law and Justice party, Poland’s largest parliamentary block, promised to follow suit and create “Budapest in Warsaw.”) Hungary’s leadership does not shy away from its authoritarian past, having established “National Day of Cohesion” in 2010 to mark “unfair and unjust dismemberment of the Hungarian nation” following the fall of Miklós Horthy’s fascist and pro-Nazi regime (1920–1944). Fidesz avowedly seeks to end “the two-party system with ongoing division as to values” and create a “permanent government” devoted to genuinely “Hungarian” values—a praiseworthy “rethinking of values” according to Vladimir Putin, but inconsistent with EU membership (Kirchik, 2017). In a May 2017 poll of residents in Hungary, Czech Republic, Slovakia, and Poland, substantial minorities in each country also think that the EU is pushing them to abandon traditional values, and Russia has taken the side of traditional values (Center for Insights in Survey Research, 2017).

Fearful of undermining the mission to escape from the chauvinism and xenophobia that fed two world wars, many Western leaders and press simply denounce national identity and cultural preference as “bigoted” or “racist,” and show an ostrich-like blindness to panhuman preferences for one’s own identity. There is also willful avoidance of unpleasant facts. In Europe, for example, the mass of immigrants come from societies whose large majorities oppose the liberty and Westerners as “greedy” and “immoral” (World Economic Forum, 2016; Pew Research Center, 2017). As a result, the political field is left wide open to those groups that address the cultural differences that leaders and the press ignore, namely, ethnonationalist groups of the alt-right, and the far-right’s less overtly racist alt-light defenders of “Western culture” against the onslaught of Islam, migrants, liberals, feminists, gays, and globalists.

In *The Descent of Man*, Darwin (1871, p. 166) cast devotion to one’s own group as the virtue of “morality . . . the spirit of patriotism, fidelity, obedience, courage, and sympathy” with which winning groups are better endowed in history’s spiraling competition for survival and dominance. Across cultures, the strongest forms of primary group identity are bounded

by sacred values, such as unwillingness to sell out one's religion or country, that are immune to material trade-offs. "Is it not that God and society are one and the same?" French sociologist Emile Durkheim (1912) famously conjectured. Through imagined kinship and faith beyond reason, religions enable strangers to cooperate in a manner that gives them an advantage in competition with other groups. This has been especially true since the advent of the "Axial Age" more than two millennia ago, when large-scale civilizations arose under the watchful gaze of powerful divinities who mercilessly punished moral transgressors to ensure that even strangers in multiethnic empires would work and fight as one (Norenzayan, 2015). Call it "God" or whatever secular ideology one prefers, including any of the great modern salvational *-isms*, such as colonialism, socialism, anarchism, communism, fascism and liberalism. This commitment to a transcendent ideal is "the privilege of absurdity to which no living creature is subject, but man," as Thomas Hobbes (1651/1901) wrote in *Leviathan*. Indeed, humans make their greatest exertions and sacrifices, for ill or good, for the sake of ideas that give a sense of significance. In an inherently chaotic universe, where humans alone among organic species recognize that death is unavoidable, there is an overwhelming psychological impetus to overcome this tragedy of cognition: to realize "why I am" and "who we are."

Often such values are attributed to Providence or Nature, and embedded in notions whose meaning one can never quite pin down, and which cannot ever be definitively verified or falsified by logic or empirical evidence (e.g., "God is great, bodiless but omnipotent" or "Free markets are always wise"; Atran, 2002, 2007; Atran & Henrich, 2010). Thus, while "sacred values" intuitively denotes religious belief, as when land or law becomes holy, it also includes the "secularized sacred," as when ground or rights become hallowed (think Gettysburg or the Bill of Rights). Consider the quasi-religious notion of the Nation itself, ritualized in song and ceremony, and sacrifice. Or take those "self-evident" aspects of "human nature" that humankind is supposedly endowed with, such as "inalienable rights of life, liberty and the pursuit of happiness." In the initial draft of the Declaration of Independence, Thomas Jefferson deemed these right "sacred," which Benjamin Franklin later made "self-evident." In fact, such rights are anything but self-evident and natural in the life of our species. For example, cannibalism, infanticide, slavery, oppression of minorities, and male

domination of women were more standard fare. It wasn't inevitable or even reasonable that conceptions of individual freedom and equality concocted by 18th-century European intellectuals should emerge, much less prevail. They did only through revolution, intensive social engineering, economic competition, and belief in "just war."

The "Clash of Civilizations" is an idea born in the intellectual circles of Harvard and *Foreign Policy*, then purposely nurtured both by al-Qaeda and ISIS and many who oppose them, including xenophobic ethnonationalist movements that play off them (Huntington, 1996). It is a woefully misbegotten idea for our times. For transnational *jihadi* terrorism and right-wing violent extremism represent not the resurgence of traditional cultures, but their collapse, as young people unmoored from millennial traditions flail about in search of a social identity that gives personal significance and glory. This is the dark side of globalization that I alluded to earlier. Individuals radicalize to find a firm identity in a flattened world. In this new reality, vertical lines of communication between the generations are replaced by horizontal peer-to-peer attachments that can span the globe, albeit in vanishing narrow bandwidths of information (Mesoudi, [Chapter 5](#), this volume).

Civilizations rise and fall on the vitality of cultural ideals, not material assets alone: "What is the other commonwealth that remains standing now that the mundane commonwealth, embodied in the Roman Empire, has fallen?" asked Augustine after the Visigoths sacked Rome over 1,500 years ago; only "The Republic of God," he surmised, would endure under whatever material guise. With the defeat of fascism and communism, have our lives defaulted to the material quest for comfort and safety on ever-shifting sand? Is this endless, despiritualized gambling for gain enough to ensure the security, much less triumph, of the open societies that we seem to take for granted, and believe our world should be based on? Reenchantment and perhaps communitarian rerooting of our own once-transcendent values in an engaged and educated citizenry for the cooperative pursuit of individual liberty and happiness may be the key existential issue for our futures. For some, rerooting of our own values of representative government, with equal opportunity and justice before the law and unfettered debate, may provide a way forward in life. Preserving what is left

of the planet's fauna and flora and avoiding environmental catastrophes may offer a new course for others.

Social Messaging

Yet no countervailing message will spread in a social vacuum. The means of engagement are critical, requiring intimate knowledge of, and participation in, communities at risk. The “counternarrative” strategies developed in think tanks and used by governments are largely ineffective. They try to dissuade youth with mass negative messaging. “So DAESH [ISIS] wants to build a future. Well, is beheading a future you want, or someone controlling details of your diet and dress?” As I noted in an address to the UN Security Council: Can anyone not know about DAESH's practices already? Does it really matter to those drawn to the cause despite, or even because of, such things?”

In contrast, the Islamic State may spend hundreds of hours enlisting single individuals and their friends, empathizing instead of lecturing, turning personal frustrations and grievances into moral outrage. ISIS understands that young people empathize with each other; they generally don't lecture (Atran, 2010b, 2015). From Syria, a young woman messages another: “I know how hard it is to leave behind the mother and father you love, and not tell them until you are here, that you will always love them but that you were put on this earth to do more than be with or honor your parents. I know this will probably be the hardest thing you may ever have to do, but let me help you explain it to yourself and to them.”

As one Imam who was a former recruiter for ISIS explained to me, “The young who came to us were not to be lectured at like witless children; they are for the most part understanding and compassionate, but misguided. We have to give them a better message, but a positive one to compete. One in our religious frame. Otherwise, they will be lost to Daesh.” If we ignore these passions, we risk fanning them, to our likely detriment and that of others across the world.

From *jihadis* in Europe to white supremacists in the United States (who are responsible for 73% of U.S. terrorist attacks since 9/11), people most susceptible to joining radical groups are youth in their teens and 20s seeking

community and purpose (U.S. Government Accountability Office, 2017; The International Alternative Right, 2017). The attraction of community is especially keen where there are sentiments of social exclusion or community collapse, whether or not accompanied by economic deprivation. Purpose most readily propels action and sacrifice, including willingness to fight and die, when it is perceived in defense of transcendent values that are dissociated from material risks and rewards, costs or consequences. Nevertheless, it would be wrong to assume that absence of community and purpose, or any other root cause, is a sufficient or even necessary determinant of “radicalization.” Most people lacking either or both community and purpose do not radicalize, much less go on to violence. There are myriad intervening environmental factors that can and do move people to violence. These range from one’s individual psychological vulnerabilities and stage in life, to particular political and social conditions such as war and religious revival, to friends and acquaintances who happen to be around.

And then there is the novel effect of social media. The rise of social media has allowed people who might want to be part of extremist movements to adhere without incurring the costs previously associated with physically joining. As political scientist Richard Hasen describes it, social media lower “the collective-action problem” of an individual going it alone because you can see that there are people out there like you (Hasen, 2018). Psychologist Molly Crockett (2017) notes that outrage-inducing messages appear to be more prevalent and provocative online than offline, with social media magnifying its triggers and reducing its personal costs. Moreover, research by sociologist Mark Granovetter (1978) shows that once an expected threshold of there being people like you is appreciably surpassed, then the number and pace of people who join the fold can rapidly ratchet up. Thus, the *Daily Stormer* website could boast in September 2017 that before Google and other major Internet sites banned it, “We used to be the biggest pro-white publication in the history of the world. With six million monthly unique visitors, we trounced the circulation of the Third Reich’s most popular tabloid *Der Sturmer*, which had 250,000.”

Although social media have been a check on repressive governments, they have also served to undermine democratic consensus and raise the risk of moral corruption through rapid, unfettered diffusion of fake news,

conspiracy theories, and other forms of propaganda. With the decline of public-service national and local news to provide a consensus about reality, false information encourages people to form mistaken beliefs about the world that are skewed to their prejudices. Here, intimate engagement to thwart the spread of the alt-right needs to occur at multiple levels, including the hands-on social engagement that helps turn youth away from local gangs, reconstituting local news as a public service for citizens, and convincing national media and Internet giants like Google and Facebook that the First Amendment right of individuals to information may not apply equally to any source without caveat, such as the Russian government seeking to sway our elections or hate groups hell-bent on ethnic cleansing.

Community service work and social media interventions both need to be involved in any serious effort at reducing threats from violent extremism. This should not be to the detriment of either, and in mixes and degrees adapted to the groups at hand. Preliminary evidence with community service workers from the United States shows increasing reliance on social media, which need not be detrimental to direct community work (A. Hoffman, 2017). Nevertheless, there is a significant correlation between perceptions of importance of social media and reduced importance of community work, despite the fact that community service work most clearly increases perceptions of understanding among ethnically diverse populations. Moreover, criminologist David Kennedy (2012) has demonstrated significant homicide-reduction among gangs and drug crews in the United States through community work. Based on his observations that offenders operate in communities in groups, he spearheaded a program in cities across the United States that brings these groups into contact with respected community members, social services, and law enforcement officials, who aim to keep everybody alive and avoid arrests.

In Al-Mahrah Governorate in Yemen, Middle East scholar Elisabeth Kendall (2016) initiated a campaign to enlist youth in community service and development work, initially relying mostly on print media and direct community engagement. But she found that 57% of al-Qaeda Twitter feeds in the province were directed toward development projects, often focusing on youth (only 3% concerned punishments). Now, her intervention work increasingly also uses social media to promote school initiatives for peacebuilding, environmental cleanup, and so on, generating wide

involvement of local youth and leaders. Learning and adapting from how al-Qaeda (and ISIS) approach social services and charity work appears to offer greater success against extremist calls than many top-down, Western-funded development projects run by a “rampantly corrupt kleptocracy” or military actions that “kill people, not ideas” (Kendall, 2016).

To understand the intricate networking of people and ideas, as well as susceptibility to social media, requires an epidemiology of radical notions in host social networks (Bond & Bushman, 2017). Although we may never be able to accurately predict which particular people will break into violence or when (and statistics have no predictive power for individual cases), we do know some of the main facilitating conditions, such as weakened or collapsed community structures and moral authority. Where these conditions are most acute, and when there is perceived opportunity to break clear into newfound community and purpose, there we will find susceptibility to radical ideas. Such devitalized communities are potentially host to any number of socially disruptive and debilitating pathogens. These include drug trafficking and crimes that garner local support as forms of social resistance in a hostile environment but which only serve to further enfeeble communities, for example, “Robin Hood” actions that take from the rich or cheat outsiders, or vigilante activities against young women perceived to violate norms of modesty or chastity. To help these communities reject the ill, we need the individuals in those communities to rebuild their sense of community and purpose, just as the *jihadis* and far-right extremists aim to do, but in ways that better fit their lives and ours.

CONCLUSION: CIVILIZATION ENDURES VIA CULTURAL IDEALS

George Orwell, in his review of *Mein Kampf* (1940/1968), described the essence of the problem of radicalization: “Mr. Hitler has grasped the falsity of the hedonistic attitude to life. Nearly all western thought . . . certainly all ‘progressive’ thought, has assumed tacitly that human beings desire nothing beyond ease, security and avoidance of pain.” In such a view of life, there is no room for greatness and glory, which, as Darwin noted, motivates heroes and martyrs to motivate others to survive and even triumph against great

material odds. “Hitler knows . . . that human beings don’t only want comfort, safety, short working-hours, hygiene, birth-control and, in general, common sense; they also, at least intermittently, want struggle and self-sacrifice.”

At the 2017 World Economic Forum in Davos, Switzerland, where I presented some of our research findings (Atran, 2017), I had the impression that most people in attendance thought that the vicious spiral of *jihadism* and xenophobic ethnonational populism were just atavistic blips in the ineluctable progress of globalization that were destined to soon go away. That to me was the most worrisome feature of Davos, whose denizens basically run the world (or try to). Few there seemed willing to change their behavior. They seemed to view the left-behinds of the dark side of globalization as simply losers who might be given a handout when robotization denies them any chance for a decent living.

To end these worries, there was earnest talk among the spectacularly wealthy of a universal guaranteed income for the economically disadvantaged. Yet poor people rarely initiate violent overthrows of established order (Mani, Mullainathan, Shafir, & Zhao, 2013). Indeed, a guaranteed income for people without purpose or significance in life would more likely radicalize them than create quiet sheep. And providing jobs that deny people dignity or the dream of a worthy life likely would fare no better.

We need a strategy to redirect radicalized youth by engaging with their passions for a better cause, rather than by ignoring or fearing them, or satisfying ourselves by calling on others to moderate or simply denounce them. Of course, there are limits to tolerance, and dangers of worse violence in appeasement of the intolerable. Neither reason alone nor modesty in aspiration will ever trump the passions in persuasion. And our partisan divisions include real differences in values that many of our politicians and pundits hype and ply into existential threats for their own fame and gain. Perhaps few of us will ever be altogether free from the anxiety of never-ending change and choice that favors escape into the absolute, and into the hopeless delusion of never-changing ways of life that can only lead to greater dread of difference in others. But there are still vast common grounds of shared passions and ideas that exist and can be created in a nation and a world where all but the too-far-gone can live life with more than a minimum

of liberty and happiness, if given half a chance. It is for this chance that some of our forebears fought a Revolution, a Civil War, and World Wars.

The times arguably call out for transformative engagement of civil society, scientists, and government to address problems of violent extremism and transnational terrorism.¹⁵ They call out as well for empirical exploration and hypothesis testing of the resilience of our values and their potential for eliciting commitment to the common defense. Scientists need to work together, across disciplinary boundaries. Governments need to fund the work, while also keeping enough distance to ensure scholarly independence. The needed resources are trivial compared to overall government expenditures on the topic, and minuscule compared to the stakes riding on its resolution. Without those resources, administered in appropriately structured programs, we will be choosing to forfeit a critical opportunity to understand our most committed adversaries and to respond effectively.

NOTES

1. Allison writes: “A few months from now, a newly elected president will be thinking about how he—or she—will deal with ISIS. . . . A serious review would begin with recognition of a brute fact: a decade and a half beyond the 9/11 attacks and President Bush’s declaration of a ‘War on Terrorism,’ the United States undoubtedly faces more terrorists determined to do harm than when this effort began.”

2. Such interaction has also benefited DoD’s Joint Improvised-Threat Defeat Organization (JIDO) in its ability to deal with improvised explosive devices (IEDs); information is available at www.jieddo.mil.

3. Although the Taliban claim credit for this saying, the sentiment recurs in many situations throughout history.

4. For information, see www.artisinternational.org.

5. After 9/11, numerous university-based basic research initiatives focused on terrorism, including decapitation strategies. For example, using multiagent network analysis to monitor and model changes in al-Qaeda, such as those following the breakup of the group responsible for suicide bombing of the U.S. Embassy in Tanzania, one research team found that eliminating leaders who are central actors (having the most ties to other groups members and to other groups) can produce more adaptive responses in the overall network “healing” process than elimination of less central actors (Carley, 2003). According to political scientist Robert Pape (2003), leadership decapitation has only “meager success,” because not all or even most leaders can be found, their death during war brings less change than anticipated, and succession is unpredictable. Academic consensus tends to consider decapitation a counterproductive, “misguided strategy” (Jordan, 2009). Although this research serves as an important corrective to the USG’s initial overreliance on decapitation to combat terrorism—whether through elimination or capture—there is little systematic evidence for any broad relationship between leadership removal and reduced counterterrorism or counterinsurgency effectiveness. Much

may depend on the organizational structure involved (strictly hierarchical vs. diffused responsibility), the inspirational role of the leaders targeted, extent of leadership removal, and so forth. For example, studies suggest that leadership removal was ineffective, because it did not prevent suicide attacks and spread of the Palestinian Intifada against Israel in 2002–2003. However, field interviews with Hamas and Israeli military leaders, and time-lag studies associated with Israel’s “Targeted Killing and Apprehension Program,” indicate that removal of Hamas leaders directly responsible for suicide attacks systematically preceded pronounced changes in Hamas’s strategy from early 2004 on: toward less direct and sustained military confrontation with Israel, including drastic reduction in attempted suicide attacks (Davis, 2016, pp. 109–116).

6. According to former CIA Director George Tenet: “We could never verify that there was any Iraqi authority, direction and control, complicity with al-Qaeda for 9/11 or any operational act against America, period” (Fager, 2007).

7. Information available at esoc.princeton.edu.

8. For Minerva, \$10 million was added to \$18 million already budgeted for fiscal year (FY) 2016, but again reduced to \$18 million for FY 2017.

9. M. R. C. Greenwood, Chancellor University of California, Santa Cruz, cogently argues that “balancing the perceived risks of open access with the risks to the health and vitality of the research community is exactly the kind of issue that calls for a new partnership between the research community and the government.” That partnership is lacking for dealing with terrorism, in part because universities and government rely on institutions that never imagined dealing with transnational terrorists and suicide bombers, and which lack flexibility to face a problem that is changing how societies seek security and interact (U.S. Senate, 2002).

10. Three-way interaction, $F_{1,808} = 13.74, p < .001, \epsilon^2_p = .02$.

11. “Your homeland in this long struggle, represents a sacred value” (Öcalan, 2011, p. 104).

12. According to Brigadier General William Turner, a Deputy Commander of the U.S.-led coalition offensive against ISIS in Mosul: “ISIS as a whole is a cornered force. . . . They are fierce fighters, there is a core of ISIS fighters that are fighting to death” (ARA News, 2017).

13. Pairwise comparisons with Bonferroni tests $p < .001$ compared to remaining conditions.

14. The study of 580 terrorism convictions in the United States found that that only 9% concerned genuine *jihadi* threats; 55% of all convictions involved a facilitating government undercover agent. In some cases there was no indication that the convicted “terrorist” had prior sympathy for *jihadi* terrorism or was capable of committing a terror act without extraordinary inducement by the government (Norris & Grol-Prokopczyk, 2015).

15. Following the November 2015 Paris attacks, France’s National Center for Scientific Research (CNRS) asked academics for projects to help society better understand and cope with violent extremism (Pain, 2015). Possible coordination between large-scale research initiatives on transnational terrorism were under discussion, including between Minerva, the CNRS, and the UN Counterterrorism Committee (UNCTC); however, no serious collaborative efforts have so far resulted. Researchers and governments are often unaware that competition and oversight for basic research awards from DoD (“basic” 6.1 as opposed to “applied” 6.2 and 6.3 funding) operate much as they do for the other main supporters of basic research in the United States (National Institutes of Health, National Science Foundation), based upon peer review of empirically grounded and theoretically innovative proposals. For example, the Air Force Office of Scientific Research has contributed basic research funding to 78 Nobel laureates over the past 60 years. On average, these laureates received this funding 17 years prior to winning their Nobel awards.

CHAPTER 32

Religious Cultures and Religious Conflict

Adam B. Cohen and Steven L. Neuberg

In this chapter on religion and religious conflict, we take the approach that religions are cultures. We discuss where religion comes from, and how we can understand religious universality, along with variation. We then focus on this variation in religious cultures, covering topics such as morality, work ethic, and prejudice, and discussing religious dimensions as mediators of religious group differences. Next we review work and theory about the relation of religious identities to other kinds of cultural identities, including national identities and economic variables. We consider a variety of perspectives, including whether other identities are best thought of as confounds or whether they combine with religion to produce unique cultural identities. We also consider the relation of theories about religion with theories about individualism and collectivism, considering whether religious groups differ in individualism and collectivism, whether we need other variables to capture religious differences, and whether religion is partly responsible for countries' differences in individualism and collectivism. Finally we consider religious conflict, in light of the previously discussed issues and research.

Religion is more than sets of beliefs held in individual minds. Rather, religions are cultures, comprising systems of values, practices, identities, norms, institutions, and all the other hallmarks of cultures. In this chapter, we explore what it means to conceptualize religion as culture and the implications of such a conceptualization.

We begin by exploring why certain defining features of religion are ubiquitous across human societies. We discuss how evolution has provided

humans with the capacity for religion, presenting perspectives positing that religion exists as a by-product of other adaptations or as an adaptation itself.

We then move to characterize religion as culture. This approach implies that religions can vary from each other, and we consider this variation, in terms of features related to morality, work ethic, and prejudice, and explore how particular dimensions of religion may mediate religious group differences.

Just as other forms of cultural identity interact with each other to shape beliefs, styles of thought, and behavior, we explore the ways in which religion interacts with other cultural identities, including those linked to national identities. For example, is the culture of American Judaism made up of some proportion of American psychology plus some proportion of Jewish psychology? Is American Judaism its own cultural identity, not reducible to some proportion of Americanness and some proportion of Jewishness?

We then relate theories of religion to one of the most studied variables in cultural psychology: individualism–collectivism. To what extent do religious groups differ in individualism and collectivism? Is religion partly responsible for national differences in individualism and collectivism?

We next explore whether, and how, religion plays into conflict. Building on many of the concepts and findings mentioned earlier, we discuss the ways religion shapes intragroup dynamics (e.g., identities, commitments, social control mechanisms) and group motivations to facilitate (or potentially inhibit) both interreligious conflict and conflict based on other distinctions (e.g., interethnic, international).

We conclude with some insights for future directions. All in all, our intention is to summarize what is known about religion as culture and point to important, theoretically interesting directions for future work.

THE UNIVERSALITY OF RELIGION

Why have humans the world over evolved the propensity to be religious? Does religion serve any adaptive or quasi-adaptive functions? To what extent might applying an evolutionary logic to the existence of religion help

us understand religious variability across and within individuals and groups?

Research on the universality of religion has become an active area of research, with major theoretical strides. Consider that beliefs in various kinds of supernatural agents—such as ghosts, ancestor spirits, or gods—are present in all societies, and people perform rituals to curry their favor or sway them to behave in certain ways (Bulbulia et al., 2008; Schloss & Murray, 2009). One view is that such beliefs and rituals are probably not adaptations themselves, but by-products of cognitive systems that evolved for other purposes (e.g., Atran & Norenzayan, 2004; Boyer, 2001).

For example, we may believe in supernatural agents because there were fitness benefits to effectively detecting—even at the risk of sometimes overdetecting—active agents in the environment. If one hears a rustling noise coming from the brush, and assumes incorrectly the presence of a tiger, this would be an error—but would cost only a few calories spent escaping from a nonexistent threat. In contrast, to assume incorrectly that the noise was merely the wind moving branches, when in fact a tiger is present, could be fatal. Signal detection systems are designed to minimize the most costly of errors (Haselton & Nettle, 2006; Nesse, 2005). Because not detecting an actual tiger is so much more costly than erroneously presuming that one is lurking in the bush, the threshold for agency detection is set low. We are equipped, some have proposed, with a hyperactive agency detection device that led our ancestors to assume that supernatural agents (e.g., spirits, gods) were responsible for hard-to-explain natural events, such as storms, earthquakes, and the behaviors of animals (Barrett, 2004).

We don't merely believe in supernatural agents; we also often feel attached to or estranged from them. For Kirkpatrick (1999), our evolved tendency to feel attachment to our parents, children, and romantic partners can be extended to supernatural agents, and we can feel securely or anxiously attached to God as well.

Other approaches suggest that religion may be more than just a by-product of other evolved adaptations, such as agency detection and parental attachment, that it may be an adaptation itself, at least at the level of the group (Wilson, 2002). Supernatural agents are often attributed specific mental features that are useful for addressing challenges of human sociality (Gervais, 2013; Norenzayan, 2013; Shariff, Purzycki, & Sosis, 2014). For

example, as societies grow larger, it becomes more difficult for individual group members to monitor others' behaviors—to catch those who are uncooperative, who cheat them, or who harm them in other ways. This challenge may be partially solved by “outsourcing” the monitoring of other people's behavior to high, moralizing gods that will punish people for behaving in antisocial ways. Just as group members' behavior is ostensibly more prosocial while under the observation of other group members who have the ability to punish antisocial behavior, group members' behavior should be similarly prosocial if they believe that their behaviors are being observed by a monitoring, punishing god.

Consistent with this reasoning, people believe that these gods prioritize their own thinking toward the domain of social relations. For example, although Americans believe that God is equally omniscient in all ways, they are quicker to say (in a reaction time study) that God has socially strategic knowledge relevant to cooperative group living (e.g., whether Steve cheats on his taxes) and slower to say that God knows socially irrelevant knowledge (e.g., how many avocados Steve has in his refrigerator) (Purzycki et al., 2012). Moreover, because the value of believing in monitoring and punishing gods is ostensibly greater for members of large-scale societies—in which personally monitoring others' behaviors is difficult, and belief in such gods would be especially useful for inhibiting antisocial behavior—we would expect greater beliefs in these gods in large-scale societies than in small-scale societies (in which individuals have an easier time monitoring one another); this is indeed the case (Atran & Henrich, 2010; Shariff, Norenzayan & Henrich, 2009; Norenzayan, 2013).

Evidence demonstrating the strong distrust many feel toward atheists is also consistent with the idea that believing in moralizing, punishing gods facilitates intragroup cooperation. Because atheists don't believe in moralizing and punishing gods, the reasoning goes, they may be more likely to believe they can get away with antisocial behavior and may therefore be more likely to attempt it. The stigmatization of atheists can therefore be seen as a form of social control designed to enhance intragroup cooperation (Gervais, Shariff, & Norenzayan, 2011).

In several ways, then, religion (at least as characterized by belief in moralizing, punishing gods) is likely to make group members more cooperative with one another. This intragroup cooperativeness facilitates the

ability of groups to compete successfully against other groups. Religion may therefore be adaptive at the group level of analysis (Wilson, 2002), helping us better understand the coevolution of large-scale societies and highly moralizing gods.

Other features of religion may also support cooperation. Religious behaviors and rituals affect co-religionists in important ways. Synchronous activities, such as religious rituals, make people feel more cooperative, more connected to the group, and better able to fend off threats from outgroup members (Wiltermuth & Heath, 2009). Extreme religious rituals, such as fire walking, are particularly emotionally evocative and enhance prosociality—even when individuals only watch them (Xygalatas et al., 2013)—perhaps because such rituals convince observers that the actors sincerely believe (Henrich, 2009).

Religious behaviors and participation in rituals may also promote cooperation as costly signals—as metabolically or behaviorally expensive, hard-to-fake communications (broadly conceived) that one is a good group member. Just as a peacock's extravagant tail or a ram's elaborate horns signal genetic quality, religious practices such as ritual scarification and dietary restrictions may signal commitment to one's religious group—that one can be counted on when push comes to shove (Sosis & Alcorta, 2003). Consistent with this, Hall, Cohen, Meyer, Varley, and Brewer (2015) experimentally manipulated the apparent costliness of a Christians' behaviors (e.g., whether they gave to Christian charities, adhered to religious dietary restrictions for Lent) and found that these behaviors increased Christian participants' trust in their co-religionists.

In contrast, one might expect that people would trust members of religious outgroups less when they costly signal. After all, if costly signaling suggest that they are especially good members of their (out)groups, they might be a threat. Interestingly, this latter prediction turns out to be wrong: The Christian participants in the earlier experiment also trusted a Muslim man more if he costly signaled by giving to Muslim charities or adhering to *halal* dietary customs (Hall et al., 2015). One possibility is that costly signals are perceived more as indications of good character than as signals of commitment to one's circumscribed ingroup. Follow-up work has indeed suggested two reasons why such behaviors increase trust. One is that religious behaviors are seen as signals of integrity (Ellis et al., 2018); another

is that religious people are perceived to live committed lives, reproductively, and thus to be dependable and nonimpulsive (Moon, Krems, & Cohen, 2018). One might be cautious of overgeneralizing these results and interpretation, however, if, for example, it mattered that the subjects were (potentially highly tolerant and multiculturally aware) Western, educated college students (Henrich, Heine, & Norenzayan, 2010; Sears, 1986).

The previous discussion makes clear that certain aspects of religion—beliefs in punishing gods, costly ritualistic practices—serve a function of enhancing intragroup trust and prosociality. The usefulness of religion as a facilitator of social control is further supported by research showing that when alternative forms of effective social control exist, religion seems less necessary to people. For example, people with stable governments seem to need religion less (Kay, Gaucher, Napier, Callan, & Laurin, 2008). This apparent “substitutability” of effective institutions for religion may help explain why many modern secular societies with strong and competent governments arc toward increasing atheism (Norenzayan, 2013).

Religion potentially serves other functions, too, such as providing greater meaning and explaining the mysteries of the world. With the advent of formal science, however, these functions of religion are increasingly usurped as well, reducing the number of people who believe that religion is necessary. An interesting empirical demonstration of this comes from Preston, Ritter, and Hepler (2013), who show that people given strong neuroscience explanations for psychological states believe in a soul less, whereas people given weak neuroscience explanations believe in a soul more. Although there are many ways of thinking about how religion and science relate to each other (Barbour, 1997), many people do seem to hold the perhaps intuitive belief that religious and scientific explanations must be in opposition to one another.

The previous discussion helps explain the cultural ubiquity of religious beliefs and behaviors, and why big gods are so common in large societies—they facilitate intragroup cooperation. That said, what accounts for the fascinating diversity across cultures of specific religious beliefs and specific behaviors and customs? To begin exploring this question, K. Johnson, Li, and Cohen (2015) considered how fundamental, evolved motives (e.g., self-protection, mate acquisition, kin care, coalition building; Kenrick, Li, & Butner, 2003) might shape dimensions of religion, including beliefs about

supernatural agents, rituals, community structures, and moral orders. For example, they hypothesized that people or groups chronically or situationally keyed in on self-protection might believe in a mighty warrior God, whereas those keyed in on raising children might be more inclined to believe in the Virgin Mary, and that these differences might affect their values and behaviors. They also generated hypotheses about religious food practices that might reflect considerations of disease avoidance, status, and reinforcing ingroup–outgroup boundaries (see also A. Cohen, Gorvine, & Gorvine, 2013; K. Johnson, White, Boyd, & Cohen, 2011). It certainly does seem plausible that foods carrying a significant risk of food-borne illness (e.g., pork carrying trichinosis) could encourage religious prohibitions against consuming that food, but we hasten to add that many people’s religious understanding of these prohibitions would probably not be about disease, but about tradition and adhering to divine commandments. Nonetheless, it would certainly be interesting to know if priming disease, or status, or coalitional motivations would make Jews or Muslims feel that there is more religious value in avoiding pork. To our knowledge, such ideas have yet to be directly tested.

The foregoing gives us a nice example of the complexities of thinking about how culture and evolution dynamically create and are affected by religious beliefs and behaviors (though we are, of course, not the first to claim that evolution does not, simplistically, create universal tendencies or instantiations of behavior; e.g., Crawford & Krebs, 2008; Kaplan & Gangestad, 2005; Kenrick et al., 2003; Tooby & Cosmides, 1995). Indeed, it is always difficult to determine whether any trait is an adaptation, by-product of other adaptations, or the result of some other kind of process; this is certainly the case for religion. Nonetheless, considerations of origin are important, as they help us better explore a variety of questions: What kinds of religions are likely to emerge, and under what circumstances? For what kinds of people is religion especially valuable? What factors are likely to shape the stability and developmental trajectories of different kinds of religions, or determine their demise? By thinking about such issues within the context of religion, we might be able to provide a model for thinking about how other kinds of cultures might emerge, fade away, or be adaptive or not for various kinds of people in various kinds of circumstances.

RELIGIONS AS CULTURES

Before people took culture seriously in psychology (A. Cohen, 2009), psychologists often assumed that people are fundamentally the same everywhere. It was a key and wide-ranging insight that culture profoundly affects people's psychological tendencies (Fiske, Kitayama, Markus, Nisbett, 2002). The analogous insight has yet to be fully appreciated among people who study religion. Much work in the psychology of religion often tacitly or explicitly assumes that religions are essentially the same, or religious people are essentially the same, and that (for example) a religious motivation that is valued in one religious group is probably valued across all kinds of religious groups (A. Cohen, Hall, Koenig, & Meador, 2005). There is some truth to this point of view; for example, religious people, regardless of their particular affiliation, hold somewhat similar patterns of values, such as valuing tradition and conformity over self-direction or materialism (Schwartz & Huisman, 1995; Kim & Lawrie, [Chapter 10](#), this volume).

Nonetheless, there is great variation among religious people's motivations, values, attentional processes, and personalities, and much of this variation can be coherently explained. In particular, religious affiliation and the various "features" of religion (doctrine, rituals, etc.) act as cultural influences, shaping and being constituted by psychological tendencies (A. Cohen, 2009).

The idea of religion as culture has deep roots. As Weber (1930) discussed in his classic sociological work *Protestant Ethic and the Spirit of Capitalism*, Calvinist Protestantism engenders culturally unique ideas about the relation of worldly success and salvation. Worldly success was a clue that one was predestined to be saved and go to heaven, rather than be damned and go to hell. These cultural notions still affect the work orientation of people who affiliate with Christian traditions rooted in Calvinism, such as Presbyterians. For example, when experimentally induced to be in a work frame of mind, Calvinist Protestants (compared to other Christians) are less attentive to relational cues but more attentive to the work task at hand (Sanchez-Burks, 2002). Even under the broad umbrella of Christianity, more specific theological traditions inform features of culture. In Germany, for example, Catholics and Protestants are higher in social trust than the nonreligious, Protestants are more trusting than Catholics, and even living in a Protestant

region makes people more trusting regardless of their particular religious affiliation (Traunmüller, 2011).

Religious groups also differ in what it means to be religious. Whereas some religious groups view religion primarily in terms of personal beliefs, others consider aspects like tradition, ritual, and community affiliation to be equally important. Jews, for example, primarily characterize their religiosity in terms of their practices, whereas Protestant Christians primarily characterize their religiosity in terms of their personal beliefs (A. Cohen, Siegel, & Rozin, 2003; reviewed in A. Cohen et al., 2005).

Religious groups also vary in their values and morals. In the European Social Survey, Muslims and Christian Orthodox individuals endorse conservative values more than do Protestants and Catholics (Schwartz, 2012). Moreover, in an analysis of 27 nations, Islamic countries were stronger in family orientation than were Christian nations (Georgas, Berry, van de Vijver, Kagitçibasi, & Poortinga, 2006). Of note, affluence and the religious constituency of countries are correlated, so the results just mentioned should be viewed with caution (Georgas, van de Vijver, & Berry, 2004).

Nonetheless even within countries, religious groups also vary in their moral judgments, and these differences tend to track differences in religious doctrine. Consider variation in how people judge others' thoughts. For both Jews and Protestants, adultery—having an extramarital sexual affair—is highly immoral. For Jews, however, thoughts alone about committing adultery are not seen as morally relevant, whereas Protestant Christians consider such thoughts to be adulterous in and of themselves (A. Cohen & Rozin, 2001). This Jewish–Protestant difference in moral judgments of thoughts occurs even for thoughts that cannot be acted upon, such as thoughts about having an affair with some presumably inaccessible movie star (A. Cohen, 2003). Yet Jews and Protestants do *not* differ in positively evaluating the morality of a person who is thinking about giving a large amount of money to charity (A. Cohen & Rankin, 2004). These similarities and differences are entirely consistent with the classic cultural texts of their religions, reflecting quite nuanced understandings of Jewish and Christian theology.

In fascinating recent work, believing that thoughts can be sinful leads Protestants to sublimate their inappropriate thoughts: When made to think

sexual thoughts about a scantily clad attractive woman they were imagining as their sister, Protestants, but not Catholics or Jews, became more creative, as evident in the sculptures and cartoons they subsequently created. Moreover, Protestants with sexual issues in adolescence (e.g., obsession with sexual thoughts, conflict about sexual issues) went on to lead more creative lives as scientists, artists, and architects, as evident in secondary data analyses of the Terman longitudinal sample (Kim, Zeppenfeld, & Cohen, 2013). Again, these kinds of results suggest that belonging to different religious cultures exerts an influence on people's psychological functioning, in this case, how they handle thoughts they consider to be either unacceptable or benign.

Religion also culturally shapes more basic processes such as emotion, attention, and personality. One important stream of theory and research on religion and emotion claims that religion, like other forms of cultural influence (e.g., East–West identity), shapes the emotions people value and strive for, in accordance with ideal affect theory. For example, whereas Christians aim to experience positive, high-arousal emotions, such as joy, Buddhists strive for peaceful, calming emotional experiences (Tsai, Miao, Seppala, 2007; Tsai & Clobert, [Chapter 11](#), this volume).

Religion also shapes low-level perceptual and attentional processes and motor control, as do certain other cultural influences (e.g., Masuda, Russell, Li, & Lee, [Chapter 8](#), this volume; Nisbett & Miyamoto, 2005). For example, the Simon effect describes the phenomenon in which people do better in a visual attention control task when the location of the stimulus is matched with the appropriate motor response. Calvinist Protestants are less likely to exhibit the Simon effect than are nonbelievers, whereas Catholics were more prone to show this effect (Hommel, Colzato, Scorolli, Borghi, & van den Wildenberg, 2011). The researchers attributed these findings to the Protestant emphasis on individual autonomy, as opposed to the Catholic emphasis on social solidarity, and these findings parallel similar ones on collectivism–individualism (Boduroglu, Shah, & Nisbett, 2009).

Differences across religious groups in cognitive tendencies can even be seen in neural processing, suggesting either different neural substrates or consequences of religion. Han et al. (2008) found differences in how self-referential processing was reflected in neural activity for Christians and nonreligious participants. Specifically, self-referential processing came with

increased activity in the ventromedial prefrontal cortex for nonreligious people, but in the dorsomedial prefrontal cortex for Christian participants. Given what these areas are known to do in social cognition, Han et al. interpreted their findings as having been shaped by the Christian goal of self-transcendence. In other findings, Han et al. (2010) showed that relative to judgments about a Chinese premier, self-judgments in Buddhist participants did not create increased activity in the ventromedial prefrontal cortex, but they did increase activity in certain other areas, including the dorsomedial prefrontal cortex, rostral anterior cingulate cortex, midcingulate, and the left frontal/insular cortex. Such results suggest that the Buddhist striving to let go of the self can be seen even at the neural level (see also Kitayama, Varnum, & Salvador, [Chapter 3](#), this volume).

Accounting for Religious Group Differences

We have been discussing different religious groups (e.g., Calvinist Protestants or Buddhists) as cultural affiliations, and how these affiliations are associated with different beliefs, psychological processes, behaviors, and practices. Why, however, do these differences exist? Are there particular features we can use to better characterize religious groups, and thereby help to account for the effects of religious affiliation on these differences?

Pulling together discussions within psychology, sociology, and other fields, Saroglou (2011) argued that four features are necessary and sufficient for religion: (1) beliefs and cognitions regarding supernatural agents, (2) moral strictures, (3) rituals and emotions, and (4) group identities. Indeed, these four features seem to be meaningful and sometimes have similar correlates across religious groups.

For example, fundamentalist and orthodox approaches to religious beliefs, as opposed to a quest-like religious orientation, are meaningful constructs in groups as diverse as Christians, Hindus, Jews, and Muslims (Hunsberger & Jackson, 2005; Hood, Hill, & Gorsuch, 2009). Similarly, the distinction between intrinsic and extrinsic religiosity—that is, religiosity as internalized and a sincere master motive of one's life, versus an instrument for achieving other goals (e.g., financial benefits, social connectedness; Allport & Ross, 1967)—is meaningful for multiple religious groups,

including Protestants, Catholics, Orthodox Christians, Jews, and Muslims (e.g., A. Cohen & Hill, 2007; Flere, Edwards, & Klanjsek, 2008). And all religious groups have both traditionally religious and idiosyncratically spiritual adherents (e.g., Dy-Liacco, Piedmont, Murray-Swank, Rodgerson, & Sherman, 2009; Saroglou & Muñoz-García, 2008), as well as mystical versus more mainstream sects (Hood et al., 2001; Lazar & Kravetz, 2005).

Moreover, individual differences in religiosity correlate in similar ways with personality across several religious groups (e.g., Buddhists, Catholics, Jews, Muslims, Protestant Christians), with religiosity positively associated with Agreeableness and Conscientiousness, and negatively associated with impulsivity (Saroglou, 2010). Across many religions, greater religiousness is linked to greater self-control, predicting less alcohol and drug use and more restricted sexual expression (McCullough & Willoughby, 2009).

Across these examples, we see each of Saroglou's four features of religion represented. That these features are relevant to a wide range of religious groups means that the groups' different standings on these features may be useful for characterizing differences among religious cultures. One logical possibility is that religious cultural differences may be explained by differences in how religions prioritize these features; that is, the relative importance of these features could vary among religions, different sects within religions (e.g., Orthodox, Conservative, Reform, secular Jews), individuals within religions, and cultural contexts in the same religion (including across history; Saroglou & Cohen, 2013), and these differences in priority may help explain differences among religious cultures. For example, Christians' greater attention to thoughts about immoral actions, seen in A. Cohen and Rozin (2001), might reflect a greater emphasis on the beliefs feature of religion on the part of Christians compared to Jews.

In summary, we have proposed that viewing religions as cultures helps make sense of the ways that members of different religious affiliations have different beliefs, practices, values, perceptual tendencies, and the like. We now consider the relations of religious cultural identities to other cultural identities.

RELATION OF RELIGIOUS CULTURES TO OTHER KINDS OF CULTURES

To convincingly make the case for the importance of religious culture as a predictor of individuals' styles of thought, behavioral inclinations, and the like, it would seem necessary to rule out confounding cultural forces. If, in a hypothetical study exploring psychological differences between Buddhists and Christians, all the Buddhists were from China and all the Christians were from Canada, one might wonder whether any observed differences are attributable to religious culture or national culture. Unfortunately, this ambiguity is not hypothetical, as many studies in cultural psychology compare (for example) Easterners with Westerners, while paying little attention to other variables (e.g., religion) that are confounded with national identities.

Consider, for example, the finding from social psychology on the so-called "fundamental attribution error" (Heider, 1958; Jones & Nisbett, 1971; Kelley, 1971)—that people overweigh others' dispositions and underweigh their situational constraints when explaining their behaviors. Morris and Peng (1994) demonstrated quite clearly, however, that this tendency is far from universal; Chinese people weigh situations much more highly than do Americans. But there are religious group differences, too: Protestants in the United States are more prone to the fundamental attribution error than are U.S. Catholics, because of Protestants' greater beliefs in a personal soul (Li et al., 2012). Might religion better explain the difference between people from China and North America—a difference previously attributed to national culture? It remains to be seen.

It is not just nationality that merits thought and empirical attention when considering potential effects of religious culture. Variables such as education, social class, and ethnic identity are often confounded with religion. Frequently, controlling such variables at levels of the individual or nation explains some of the similarities and differences among religious groups, but not all. For example, one study of more than 100 countries revealed that Protestant countries were higher than Muslim ones on individualism and subjective well-being, and lower on power distance (hierarchical relations); that Protestant countries were higher than Catholic countries on secular authority and lower in uncertainty avoidance; that

Catholic countries tended to be higher on harmony and uncertainty avoidance; and that these effects existed over and above economic factors even though affluence and the religious constituency of countries are related (Georgas et al., 2004).

Other researchers have found that associations between religiosity and tolerance, attitudes toward women, and trust of government are similar for Catholics, Protestants, Muslims, and Hindus, even after economic variables, sex, age, and health were controlled (Guiso, Sapienza, & Zingales, 2003). Yet the values of a country's historical religion can often still be detected after researchers control for potential confounds such as economic development (Inglehart & Baker, 2000). And even as modern America is less religious than it used to be, its Puritan-Protestant legacy is still subtly evident even when explicitly absent. For example, implicitly priming Americans with words related to salvation made them work harder on an assigned task in the laboratory, which shows that Protestant notions of salvation are still implicitly linked to Protestant notions of work and calling (Uhlmann, Poehlman, Tannenbaum, & Bargh, 2011).

Nonetheless, to be able to claim an effect of religious variables, the answer is not as simple as demanding that within-group, cross-group, or cross-national analyses be obliged to control for nationality, ethnicity, social class, education level, democratization, secularization, or any other variables that are not explicitly religious. Sometimes such controls are appropriate but often they are not, because the relations of such variables to religious variables are often complex and subtle—and simply partialing out nonreligious variables may actually be partialing out influences of religion itself.

Considering religion and national cultures, one can view (1) religions as cultures in and of themselves, (2) religions as subcultures of national cultures, (3) national cultures as subcultures of transnational religious regions of the world, (4) religions and national cultures as conflicting with each other, and (5) new blends of religious and national cultures resulting from globalization (K. Johnson & Cohen, 2013). Thus, beyond the practical difficulty of independently measuring religion and potentially confounding variables, it is often theoretically problematic to consider religion and such variables as unrelated—to even *want* to view them as independent—because they may be historically and culturally intertwined in causal ways. For

example, researchers interested in religious differences between nations may want to partial out economic development as a potential confound. Yet, to some extent, religion shapes the economic development of nations (Hayward & Kemelmeier, 2011), and greater economic development often comes with a decrease in religion (Norris & Inglehart, 2004). Religion and economic development are neither historically nor theoretically independent. To attempt to simply separate effects of religion from effects of economic development by controlling one for the other may therefore be theoretically problematic.

At other levels of analysis, the same point about religion and national culture being entwined can be made. A religion could have the same or different effects in different national contexts, depending on factors such as the predominant religion, whether the country is religious or secular, and whether one is a member of a majority or minority group. For example, would one expect Jews in the United States to moralize thoughts similarly to Jews in other countries? Perhaps Jews in the United States would be especially unlikely to moralize thoughts, in an attempt to distinguish themselves from the Christian majority; perhaps they would be especially likely to moralize thoughts, having been affected by the predominant (Christian) view that thoughts are morally important; or perhaps Jews the world over would similarly moralize (or not), reflecting a cultural conservation of a meaningful, important principle (A. Cohen et al., 2013).

More broadly, one might ask whether being an American Jew is best thought of as some weighted combination of being Jewish and American, such that to be Jewish American is to be biculturally Jewish and American, or whether being Jewish in America is a unique cultural experience, qualitatively different than being Jewish in, say, Israel or Iran. Does nationality trump religion? Does religion trump nationality? Or, as suggested by the work of Sasaki and Kim (2011), do religion and nationality combine in a unique pattern?

Empirically, religion sometimes does interact with other identities. For example, religiosity correlates with political conservatism among Whites and Asians, but not among Blacks and Hispanics (A. Cohen et al., 2009). This may be because people partly learn, via cultural messages, what political attitudes one should hold if one is religious, and these messages may emphasize different religious values such as traditionalism versus social

justice (see Malka, 2014, for a more in-depth discussion of political cultures).

Religion also seems to operate differently depending on whether the religious group is in the majority or the minority. Catholics in Protestant countries are more likely to highlight sexually restrictive and collectivistic values than are Catholics in Catholic-majority countries (Procter & Hornsby-Smith, 2003). Whereas having a religious upbringing in a nation's dominant religion is associated with trusting other people less and holding an antiwomen bias, having a religious upbringing in a nation's nondominant religion is associated with trusting others more and being less biased against women (Guiso et al., 2003). The overall political climate also shapes effects of religion: Whereas increased religiosity predicts favorable views toward security among Catholics in Western Europe, increased religiosity predicts unfavorable views toward security among Catholics in Eastern Europe (Roccas & Schwartz, 1997), perhaps because Catholicism in those countries had been opposed by their communist governments.

Focusing on Europe, Bréchon (2003) cautioned that some apparent effects of religion (Protestant vs. Catholic) may actually reflect national effects, and attempted to deconfound these. We agree that it's important to carefully consider the roles played by many types of variables when considering possible effects of religion (e.g., national identity, economic factors, social class, majority status, democratization, education), but suggest that the meanings of relationships between religion and such variables hinge critically on the operative research question. This brings us to address the relation of theories on religion to other cultural theories.

RELATIONS TO OTHER THEORIES IN CULTURE

How do theories about religion intersect with other prominent theories about culture in psychology? Can we understand religions using the same cultural theories, or do we need specific theories of religious culture? This is not a simple question, and we don't have a simple answer. We consider this question in light of the dominant cultural distinction in cultural psychology—cultural differences in individualism–collectivism (Markus & Kitayama, 1991; Triandis, 1995). To anticipate, it is not clear to us that theorizing about

religion can be subsumed under ideas about individualism–collectivism; how useful individualism–collectivism is for understanding religious culture likely depends on the domain of interest and how broadly or narrowly one is willing to think about individualism and collectivism.

It does seem fair to summarize many previously documented religious tendencies as individualist or collectivist. Durkheim (1897/1951) believed that the greater collectivism of Jews and Catholics helped explain their lower suicide rates compared to more self-directed and individualistic Protestants. Whereas meaningful religious experiences for Protestants are often characterized by reports of life-changing, personal experiences with the divine (born-again experiences), equally meaningful experiences for Jews and Catholics are frequently about participating in a community of co-religionists, perhaps a more collectivistic viewpoint on religion (A. Cohen & Hill, 2007). Jews' religiosity is best predicted by their level of religious practice, again perhaps implying a greater collectivism, whereas Protestants' religiosity is also strongly predicted by personal belief (A. Cohen et al., 2003). When Allport (1954; Allport & Ross, 1967) proposed that it is better to be intrinsically religious than extrinsically religious, he might have been expressing an American, individualistic preference for internally motivated religion (A. Cohen, Hall, Koenig, & Meador, 2005). Moreover, although (more individualistic) Protestants seem to view extrinsic reasons to be religious as antithetical to intrinsic ones, this is not the case among Jews and Catholics (A. Cohen & Hill, 2007).

In a similar vein, recall that Protestants are more likely than Jews to condemn others for having antisocial thoughts. One might interpret this as reflecting an individualistic outlook on the part of Protestants (even one's internal, personal thoughts are relevant), and a more collectivist one on the part of Jews. For Jews, upholding commandments and social norms despite inclinations to do otherwise might be interpreted as a collectivistic tendency to place God's commandments, and the community's interpretation of God's commandments, above one's own desires.

Despite the fact that these are reasonable interpretations, should everything that cultures do be thought of as individualistic or collectivistic? This Protestant–Jewish difference, in A. Cohen and Rozin's (2001) article, was not mediated by a difference in independent and interdependent self-construals, as measured by Singelis's (1994) often-used scales. Instead, the

difference was strongly mediated by Protestants' much greater agreement that thoughts are as morally important as actions—the specific theological notion that differs between these groups regarding the morality of thoughts. Furthermore, for both Jews and Protestants in A. Cohen and Rozin's article (2001), religiosity was positively correlated with interdependence, but not with independence. If Protestantism is simply individualistic and Judaism is collectivistic, religiosity among Protestants would have perhaps correlated with independence and religiosity among Jews would have correlated with interdependence.

Thus, careful thought is needed before we ascribe religious effects to individualism–collectivism or to independent–interdependent self-construals. It has been generally noted that, although important for understanding culture, individualism and collectivism have been flexibly applied to explain almost any kind of cultural process. Moreover, like other forms of culture, religious cultures comprise diverse subcultures that may vary in individualistic and collectivistic tendencies (Brewer & Chen, 2007; A. Cohen, 2009; Fiske, 2002). Last, it's important to recognize that religion may have played an important role in shaping the development of societal individualism–collectivism (A. Cohen, 2014, 2015; A. Cohen & Varnum, 2016). For example, as far back as de Tocqueville (1835/1969) and, more recently, Bellah, Madsen, Sullivan, Swidler, and Tipton (1985), social scientists have pointed to Protestant culture and theology as reasons why America has become so individualistic. Thus, while we do think there is substantial heuristic value in describing certain aspects of certain religions as relatively individualistic or collectivistic (see also Markus & Conner, 2013), we stress that we see a dynamic causal relationship here, with individualism–collectivism not necessarily causally preceding the development of religious codes and cultures.

RELIGION AND CONFLICT

The concept of religion as culture implies that a religious group can be much more than a mere collection of individuals who happen to hold similar beliefs. Rather, religious groups may be operating coalitions, organizing and motivating individual members toward group goals and ambitions. Such

goals may place groups in conflict with one another. Indeed, intergroup conflict has long been a feature of human (and nonhuman) life. In what ways, if at all, might religion contribute to the presence (or absence) of intergroup conflict?

Religion-Based Mechanisms Facilitating Intergroup Conflict

Some theorizing has focused on religion-on-religion relations, in which clashes between religious values directly lead to conflict between religious groups (e.g., Huntington, 1993; Kaplan, 2007; Norris & Inglehart, 2004). Because values shape societal norms, policies, and laws in ways that tangibly affect people's lives, one might expect people to be prejudiced toward and discriminate against groups that endorse (or appear to endorse) values different from their own. This is indeed the case (e.g., Biernat, Vescio, Theno, & Crandall, 1996; Biernat, Vescio, & Theno, 1996; Katz & Hass, 1988; Kinder & Sears, 1981; Rokeach, 1972; Schwartz, Struch, & Bilsky, 1990). To the extent that the values held by different religious groups are believed to be incompatible with one another, one might expect religious groups to be in conflict. This should be especially the case if the groups holding incompatible values view them as sacred, and therefore not something to be compromised (Atran & Ginges, 2012).

Other approaches focus less on religion as a motivator of conflict, and more as a factor that increases the *capacity* of a group to engage other groups in conflict. These approaches claim that interreligious conflict is rarely about religion per se, theorizing instead that religion often serves to justify, provide a mask for, or merely facilitate conflict that would occur nonetheless, for nonreligious reasons (e.g., Berman, 2009; Cederman, Weidmann, & Gleditsch, 2011; Fearon & Laitin, 2003; Toft, 2007). This view would suggest, for instance, that the long-lasting "troubles" between Catholics and Protestants in Northern Ireland were rooted in conflicts of interest regarding territory or socioeconomic status, with religion playing at best a supporting role. Along these lines, consider the hypothesis that religious beliefs can be used to justify intergroup conflict that otherwise occurs for nonreligious reasons. Indeed, the history of intergroup conflict is

rife with accompanying justifications, including those citing needs to create fairness by rectifying previous wrongs, by resolving existing relative deprivations, and the like.

Religion can be a powerful source of justifications, pre or post hoc. For instance, claims of religion-based moral superiority may be used to justify conflict against others, such as when European colonizers were accompanied by Christian missionaries, ostensibly bringing salvation to benighted natives, while European corporate entities harvested resources from their lands against the wishes of the locals. Similarly, because moral purity is an important value for many religions, groups may justify “cleansing” their lands of nonbelievers by referencing religious purity concerns. Such justifications increase a group’s capacity to engage in conflict. Of course, it’s unlikely that these different explanations for the religion–conflict link are mutually exclusive; religion can potentially motivate conflict *and* provide the capacity to engage in it *and* justify it.

Specific religious beliefs and doctrine may be especially relevant for driving or facilitating conflict between religious groups, especially if these beliefs are viewed as incompatible with one another. Of course, there’s much more to religion than beliefs and doctrine. Other features of religion include practices, styles of discourse, socialization functions, organizational and communication structures, and community and institutional embeddedness (Lincoln, 2003), and these features may also facilitate intergroup conflict—not just between religious groups but also between groups defined in nonreligious terms (e.g., ethnicity, nationality, political affiliation). Many religious communities are well-organized, with leadership and authority structures, communication networks, tangible resources and mechanisms for distributing them to adherents, and the like. These organizational features increase the ability of groups to mobilize their human, financial, and rhetorical resources for many purposes—including engaging and maintaining intergroup hostilities (e.g., Gould, 1999; McAdam, Tarrow, & Tilly, 2001).

Moreover, we discussed earlier that religious groups often require costly signals of commitment from their members (Atran & Henrich, 2010; Bulbulia, 2004; Bulbulia & Sosis, 2011). These commitments include engaging in effortful personal practices (e.g., keeping the Jewish dietary laws, or keeping kosher), but they also include participating in public,

community rituals and festivals—all of which would be expected to increase the strength of ties to other group members. Such ties increase the likelihood that group members will act prosocially toward, and sacrifice for one another, and make it easier for them to punish those unwilling to do so. These inclinations constitute a valuable resource for successful intergroup conflict. And one specific religious belief may especially amplify the extent to which these social and organizational features of religion encourage conflict—the belief that a community-serving death results in a favorable eternal afterlife. One interesting implication of the role religion may play in enhancing social and organizational capacities is that even groups such as ethnicities, nations, and political parties can benefit from the social-organizational capacities provided by the religions with which they are associated.

In all, then, there are strong theoretical reasons why religion may play important roles in facilitating intergroup conflict. Moreover, as we observe conflicts around the world, many of the hypotheses about how religions may foster conflict certainly appear face valid. That said, strong empirical evidence for effects of religion on conflict is sparse, largely due to the difficulty of testing these ideas.

Religious Infusion and Intergroup Conflict

If religions are cultures, this implies that religion is, to a meaningful extent, “infused” throughout the private and public lives of adherents—shaping adherents’ social networks, creating shared social narratives and discourse that adherents use to communicate with and influence one another, bringing adherents together for community rituals and festivals, generating accepted injunctive norms for proper behavior of adherents, employing mechanisms to socialize or otherwise transmit religious beliefs and customs to new members, and the like.

Religious infusion can therefore be viewed as a meta-feature of religious culture (Neuberg et al., 2014); that is, whereas different religions may promote qualitatively different beliefs and doctrine, have qualitatively different rules and rituals, and so forth, they all, in principle, may be strongly (or weakly) infused within a community. In this sense, infusion is

not viewed as an inherent feature of any religion, as the same religion can be highly infused in one location (e.g., Catholicism in Nicaragua) but not in another (e.g., Catholicism in Austria).

Neuberg and colleagues (2014) suggested that religiously infused groups may be especially likely to engage in intergroup conflict, because they would be especially likely to possess the social, community, and organizational strengths discussed earlier. For example, more frequent participation in community events and greater use of common forms of discourse are likely to increase the salience of group norms, strengthen intragroup solidarity, enable more effective communication and coordination, elicit strong personal commitments to the group and its members, and reduce the likelihood that group members will defect from collective action (e.g., Atran & Henrich, 2010; Ginges, Atran, Sachdeva, & Medin, 2011; Ginges, Hansen, & Norenzayan, 2009). These, in turn, are likely to enhance the probability that group members will internalize existing group prejudices against other groups, and increase a group's motivation and capacity for collective action. As a consequence, groups with high levels of religious infusion may be especially poised for intergroup conflict if circumstances call for it.

This seems to be the case, as revealed in a study of 194 groups nested within 97 sites around the globe (Neuberg et al., 2014). First, although groups with values incompatible with one another were more prejudiced against one another and more likely to interpersonally discriminate against one another, this finding was moderated by religious infusion: When religious infusion was low, incompatible values did not predict groups' prejudices and discrimination. When religious infusion was high, however, incompatible values strongly predicted these forms of intergroup conflict. As a predictor of intergroup conflict in this dataset, value incompatibility required high levels of religious infusion. It's instructive that this was the case across the types of groups in the study (e.g., ethnic–ethnic, religious–religious, nation–nation); religious infusion didn't just moderate the effects of incompatible values between religious groups.

Second, whereas groups with power and resource advantages were generally more conflictual toward their lower-power counterparts—engaging in more collective violence, individual-level violence, and symbolic aggression—this effect, too, was moderated by religious infusion. Specifically, low-power groups that were also low in religious infusion

tended to avoid conflict with their powerful counterparts, a finding consistent with the deterrent effects created by power. In contrast, similarly low-powered groups that were instead *high* in religious infusion didn't avoid conflict but rather engaged it—despite the costs that such aggression is likely to bring from their high-power counterparts. These findings suggest that disadvantaged but religiously infused groups may be relatively insensitive to the low probability of their success and to the tangible costs that high-power counterparts could impose in retaliation.

This finding reveals the power of religious culture to shape the behaviors of group members even in the face of potentially huge costs. Of course, not all religiously infused, low-power groups engage in these serious, action-oriented forms of conflict. Differentiating such cases will have significant implications for theory and important applied implications for reducing violent intergroup conflict.

Can Religion Reduce Intergroup Conflict?

We have focused on theory and findings suggesting ways in which religious culture facilitates intergroup conflict. This emphasis has a long history in the psychological and social sciences. Early empirical work, largely focused on Christianity and prejudice, found that religious believers tended to be more prejudiced against outgroup members than were nonbelievers (e.g., Allport & Kramer, 1946; Hunsberger & Jackson, 2005). Other research focused on fundamentalist believers, who stand out in their negative prejudices against those believed to act in ways considered sinful (e.g., homosexuals; Hunsberger & Jackson, 2005). More recently, researchers have attended to the substantial negative prejudice directed toward atheists in the United States, which appears to be multiply determined and shaped by religious beliefs and assumptions. Survey and experimental research shows that these prejudices stem at least partially from the threats to values and social coordination that atheists are presumed to pose (e.g., Cook, Cottrell, & Webster, 2015). For example, people assigned in one experiment to read an essay designed to activate concerns about declining moral values (compared to a control essay) became more likely to report that atheists make them feel anxious and that they would discriminate against them (Cook et al., 2015).

Other work shows that antiatheist prejudices also stem partially from the belief that atheists cannot be trusted to act prosocially given that they do not believe in monitoring and punishing gods (e.g., Gervais et al., 2011; Norenzayan et al., 2016), as we mentioned earlier.

Although it's clear that religious doctrine and teachings can be recruited to motivate and justify a range of negative prejudices, and that religious culture can provide capacity to engage in intergroup conflict, the opposite also seems clear—that religious doctrine and teachings *could* be recruited to motivate and justify intergroup tolerance and acceptance, and that religious culture *could* provide capacity to engage in intergroup peacemaking. For example, most religious traditions include teachings that seemingly promote tolerance and acceptance of others (e.g., versions of the so-called “golden rule”). Moreover, individuals who take a “quest” orientation to their religious beliefs—who see religion as a personal journey toward truth, in which one doesn't expect to find simple answers to complex spiritual and moral questions—tend to be less prejudiced than those who are either intrinsically or extrinsically religious (Batson & Burris, 1994; Batson & Ventis, 1982). Further, many religious organizations have peace-making as their animating goals, and the very existence of *interreligious* tolerance-focused organizations provide anecdotal evidence for the ability of religion to diminish tension and conflict, at least at very local levels.

Unfortunately, clear evidence for conflict- and prejudice-reducing effects of religion is relatively sparse (e.g., Hall, Matz, & Wood, 2010). Some experimental work shows that people primed with religious words become more generous and honest (e.g., Pichon, Boccato, & Saroglou, 2007; Randolph-Seng & Nielsen, 2007; Shariff & Norenzayan, 2007), but other work shows that religious primes may also lead to hostility against outgroups (e.g., M. Johnson, Rowatt, & LaBouff, 2010, 2012; Saroglou, Corneille, & Van Cappellen, 2009). Preston and Ritter (2013) suggested that this lack of clarity may result from a conceptual muddling of religious concepts, some focused on the religious group and others focused on the idea of god. Thinking about one's religious group is likely to activate coalitional thinking, and therefore enhance ingroup-favoring biases. In contrast, thinking about one's god is likely to highlight beliefs about morality and the ability of one's god to monitor and punish those who act in antisocial ways, and therefore enhance beneficent behavior toward

outgroups. Indeed, in a series of studies carefully designed to differentiate between religion and god concepts, these researchers found that religion primes led participants to favor members of their own ingroups, whereas god primes led participants to favor members of outgroups.

Two lines of work by Ginges and colleagues are consistent with these findings and line of reasoning. In a study of Palestinian Muslims, Israeli Jews, Indian Hindus, Russian Christian Orthodox, Indonesian Muslims, British Protestants, and Mexican Catholics, the researchers showed that support for one form of intergroup conflict—suicide attacks against members of other groups—was predicted by attendance at religious service (an indicator of commitment to one’s religious group) but not by prayer (conceptualized as an indicator of one’s personal religious devotion) (Ginges et al., 2009). In a related program of work, Palestinian Muslim youth living in Gaza or the West Bank were given a hypothetical moral dilemma—whether to sacrifice one Palestinian man to save five children from an onrushing truck. In baseline conditions, participants were much more likely to approve of sacrificing the man for the children when the children were presented as Palestinian than when they were presented as Israeli Jews. This ingroup bias was significantly reduced, however, when participants instead were asked to think of whether Allah would approve (although the bias still remained substantial; Ginges, Sheik, Atran, & Argog, 2016).

These two lines of work, as with that of Preston and Ritter (2013), suggest that although religion tends to facilitate intergroup conflict in its coalitional forms, it has the potential to reduce intergroup conflict when the focus is on the broader prosocial, peaceful beliefs endorsed by their animating gods. In summary, it seems clear that religion plays an important role in intergroup conflict, although clarifying causal roles for religion is a challenge. Meeting this challenge will require cleanly articulating and testing the ways in which specific features of religions, thought about in cultural terms (e.g., infusion, values, beliefs about the afterlife, organizational capacity), engage or modulate specific conflict (and tolerance) mechanisms (e.g., value [in]compatibilities, competition–cooperation for resources). Datasets created to appreciate such nuances will be critical, as will research designs better able to draw causal inferences (e.g., longitudinal designs, true experiments). Of course, similar challenges characterize attempts to explore

the causal effects of other sources of culture besides religion. That intergroup conflict is so costly, however, adds practical urgency to such efforts.

CONCLUSION

We have reviewed research showing that religions have distinct practices, values, institutions, and all the other hallmarks of culture. Taking this approach, we also considered how theorizing about religions as cultures locates us within the context of cultural psychology. We've explored whether religious variables really reduce to other well-studied variables in cultural psychology, such as individualism and collectivism; how religion might combine with other cultural identities (e.g., nationality); and which features of religion might help explain why people identifying with or belonging to different religions might differ from one another in how they think, feel, or behave. Finally we have taken a religion-as-culture approach to better understand how religion facilitates or reduces intergroup conflict—not only between religious groups but also between other kinds of groups.

As has been argued elsewhere, the study of religion has a lot to offer the study of culture (e.g., A. Cohen, 2009; Tarakeshwar, Stanton, & Pargament, 2003), and we hope this chapter serves as a further example of the importance of understanding the importance of religions in various cultures, and of approaching religions as cultures. Much can be gained by applying some of the other approaches in this handbook to the study of religion. For example, the chapter by Talhelm and Oishi ([Chapter 4](#), this volume) on the ecological forces that affect culture suggests we might also examine how ecological forces affect religion. Thus, one might expect that features of the ecology could affect how central religion is to a community, how moralistic or how “tight” its rules are, how fatalistic its dogma is, how universalistic its codes for behavior are, and so on. What features of the ecology—natural or human—are conducive or not conducive to religious creativity or to religious fervor?

There are a number of potentially interesting questions that may be explored by taking the tools and approaches used to study culture and applying them to religion. Furthermore, what we learn about religion can feed back into what we understand about culture—and particularly the

development of belief systems, worldviews, and primal sense of connection to others. For now, these are matters of speculation. However, we think there is potentially much to be gained through the feedback in knowledge gained from studies of culture in general and studies of religion in particular.

About Guilford Press

www.guilford.com

Founded in 1973, Guilford Publications, Inc., has built an international reputation as a publisher of books, periodicals, software, and DVDs in mental health, education, geography, and research methods. We pride ourselves on teaming up with authors who are recognized experts, and who translate their knowledge into vital, needed resources for practitioners, academics, and general readers. Our dedicated editorial professionals work closely on each title to produce high-quality content that readers can rely on. The firm is owned by its founding partners, President Bob Matloff and Editor-in-Chief Seymour Weingarten, and many staff members have been at Guilford for more than 20 years.
